17

18 Three samples of the skarn mineral rustumite  $\text{Ca}_{10}(\text{Si}_2\text{O}_7)_2(\text{SiO}_4)(\text{OH})_2\text{Cl}_2$ , space group  $C2/c$  ( $a \approx$   
19  $7.6$ ,  $b \approx 18.5$ ,  $c \approx 15.5$  Å,  $\beta \approx 104^\circ$ ) with variable OH, Cl, F content were investigated by electron  
20 microprobe, single-crystal X-ray structure refinements, and Raman spectroscopy. "Rust1\_LCl" is  
21 a low chlorine rustumite  $\text{Ca}_{10}(\text{Si}_2\text{O}_7)_2(\text{SiO}_4)(\text{OH}_{1.88}\text{F}_{0.12})(\text{Cl}_{1.28}\text{OH}_{0.72})$  from skarns associated  
22 with the Rize batholith near Ikizedere, Turkey. "Rust2\_F" is a F-bearing rustumite  
23  $\text{Ca}_{10}(\text{Si}_2\text{O}_7)_2(\text{SiO}_4)(\text{OH}_{1.13}\text{F}_{0.87})(\text{Cl}_{1.96}\text{OH}_{0.04})$  from xenoliths in ignimbrites of the Upper Chegem  
24 Caldera, Northern Caucasus, Russia. "Rust3\_LCl\_F" represents a low-Cl, F-bearing rustumite  
25  $\text{Ca}_{10}(\text{Si}_2\text{O}_7)_2[(\text{SiO}_4)_{0.87}(\text{H}_4\text{O}_4)_{0.13}](\text{OH}_{1.01}\text{F}_{0.99})(\text{Cl}_{1.00}\text{OH}_{1.00})$  from altered merwinite skarns of the  
26 Birkhin massif, Baikal Lake area, Eastern Siberia, Russia. Rustumite from Birkhin massif is  
27 characterized by a significant hydrogarnet-like or fluorine substitution at the apices of the  
28 orthosilicate group, leading to specific atomic displacements. The crystal structures including  
29 hydrogen positions have been refined from single-crystal X-ray data to  $R1 = 0.0205$  (Rust1\_LCl),  
30  $R1 = 0.0295$  (Rust2\_F) and  $R1 = 0.0243$  (Rust3\_LCl\_F). Depletion in Cl and replacement by OH  
31 is associated with smaller unit-cell dimensions. The substitution of OH by F leads to shorter  
32 hydrogen bonds  $\text{HO-H}\cdots\text{F}$  instead of  $\text{HO-H}\cdots\text{OH}$ . Raman spectra for all samples have been  
33 measured and confirm slight strengthening of the hydrogen bonds with uptake of F.

34 **KEYWORDS:** rustumite, crystal chemistry, skarn mineralogy, crystal structure, OH-, F-,Cl- substitution, Raman  
35 spectroscopy , hydrogen bonds.

## 36 **Introduction**

37 Rustumite ( $a = 7.62 \text{ \AA}$   $b = 18.55 \text{ \AA}$   $c = 15.51 \text{ \AA}$   $\beta = 104.33^\circ$ ,  $V = 2124 \text{ \AA}^3$ , space group  
38  $C2/c$ ) from contact-metamorphosed Jurassic limestone at Kilchoan, on the northwest coast of  
39 Scotland, was originally defined as a new mineral of assumed  $\text{Ca}_3\text{Si}_2\text{O}_7(\text{OH})_2$  composition  
40 (Agrell 1965). Two metamorphic stages are reported at Kilchoan. A first high-temperature  
41 decarbonatisation stage with a high  $\text{CO}_2:\text{H}_2\text{O}$  ratio and a second hydrothermal stage with low  
42  $\text{CO}_2:\text{H}_2\text{O}$ . Rustumite occurs in a zone between spurrite dominant and kilchoanite dominant  
43 assemblages and may carry inclusions of spurrite, melilite, or its alteration products, merwinite,  
44 larnite, rankinite, and kilchoanite (Agrell 1965). The observed paragenesis provides evidence that  
45 rustumite formed during the second stage between  $500^\circ\text{C}$  and  $700^\circ\text{C}$  (Agrell 1965). Rustumite is  
46 named after Rustum Roy, well known for his contributions to science ranging from experimental  
47 mineralogy, interdisciplinary material research to science politics (Komarneni, 2011).

48 The revised end-member formula  $\text{Ca}_{10}(\text{Si}_2\text{O}_7)_2(\text{SiO}_4)(\text{OH})_2(\text{Cl})_2$  of rustumite was derived  
49 from the crystal structure solved by Howie and Ilyukin (1977) and Nevskii et al. (1979).  
50 Increased electron density at a supposed OH position was interpreted to be caused by chlorine.  
51 The structure was solved in the monoclinic space group  $C2/c$  with  $Z = 4$  and refined to  $R1 = 7.4\%$ .

52 Taner et al. (1977) reported rustumite from skarns associated with the Rize-batholite near  
53 Ikizdere, Eastern Turkey. Based on the mineralogical skarn assemblages and fluid-inclusion  
54 micro-thermometry Hezarkhani (2006) proposed two stages of metamorphism. Similar to the  
55 skarn at Kilchoan (Agrell 1965) a high-temperature contact-metamorphic event is followed by  
56 hydrothermal alteration with an aqueous fluid at ca.  $400^\circ\text{C}$ . Rustumite formed during the latter  
57 and is associated with epidote, tremolite, trabzonite, hillebrandite, tilleyte, killalaite, chlorite and  
58 low temperature vesuvianite (Hezarkhani 2006). The Cl content of rustumite from these skarns is  
59 ca. 5.4 wt.% (Hezarkhani 2006) which corresponds to 1.4 Cl per formula unit (pfu).  
60 Stoichiometric rustumite with 2 Cl pfu requires 7.59 wt. % Cl.

61 A rustumite bearing skarn near the La Negra mine, Quertaro, Mexico is formed by a  
62 Tertiary diorite intrusion in a late-Jurassic limestone host-rock (Kanazawa et al. 1997). Rustumite  
63 and wadalite associated with andradite, hydrogarnet, magnetite and calcite grew zonally within  
64 spurrite rocks. The chlorine concentration of rustumite in these rocks is 5.76 – 6.24 wt. % but still  
65 below the stoichiometric limit. Rustumite has also been found in the gehlenite-spurrite-skarn at  
66 Kushiro, Hiroshima Prefecture, Japan (Takechi et al. 2000) but analytical data are missing.

67 In addition, granitoids of the Dara-e-Noor Massif at the Kala-e-Asad deposit in  
68 Kandaghar, Afghanistan, intruded into dolomites and assimilated them. The primary gehlenite –  
69 spurrite skarn was subsequently altered to rocks containing vesuvianite, garnet and wollastonite,  
70 which were cut by veinlets of tilleyite (replacing spurrite) and rustumite (Bogomolov 1970). It  
71 was the single-crystal X-ray diffraction pattern of rustumite described by Bogomolov (1970),  
72 indexed with an orthorhombic cell (probably erroneously – due to twinning), which inspired  
73 Dornberger-Schiff and Organova (1971) and Dornberger-Schiff and Fichtner (1972) to  
74 hypothesize rustumite to be a member of an OD-groupoid family. However, the subsequent  
75 structural studies by Howie and Ilyukin (1977) and Nevskii et al. (1979) did not support this  
76 interpretation.

77 An artificial analogue of rustumite was reported from burnt waste piles, deposited in the  
78 Chelyabinsk coal basin, Southern Ural region, Russia (Zateeva et al. 2006). However, the  
79 provided electron-microprobe data (their Table 3, analyses no. 4 (E-25)) suggest an anhydrous  
80 Cl-bearing material with Ca/Si = 1.72. The Ca/Si ratio should be 2 for rustumite. Their analysis is  
81 more consistent with the composition of the new mineral rusinovite  $\text{Ca}_{10}(\text{Si}_2\text{O}_7)_3\text{Cl}_2$  (Galuskin et  
82 al. 2011). Furthermore, formation of rustumite under pyrometamorphic conditions is rather  
83 doubtful due to the low  $\text{H}_2\text{O}$  activity. Moreover, the occurrence of  $\text{Ca}_{10}(\text{Si}_2\text{O}_7)_3\text{Cl}_2$  (analogue of  
84 rusinovite) from the dumps in the Chelyabinsk coal basin has been described before by  
85 Chesnokov et al. (1994). Chemical analyses of minerals in corroded refractory materials of waste  
86 combustion plants (Pawlowski 2008) were interpreted to show rustumite. Though confirmation  
87 by X-ray powder diffraction was not successful.

88 In summary, rustumite is a rare skarn mineral, which has not been reported from  
89 anthropogenic cementitious materials. In this study, the variable chlorine-content of rustumite is  
90 investigated. The applied methods comprise single-crystal X-ray structure refinements, Raman  
91 spectroscopy, and electron microprobe analysis.

## 92 **Sample description**

93 Low-Cl rustumite (Rust1\_LCl) was found in a hydrothermally altered skarn associated  
94 with the Rize-batholite near Ikizdere, Eastern Turkey. Detailed description of the geological  
95 context is provided by Taner et al., (1977), Sarp and Burri (1986), Sarp and Burri (1987),  
96 Hezarkhani (2006). The examined sample is part of the mineral collection of the Natural History  
97 Museum in Geneva, Switzerland (NHM Geneva accession number (477/051). Rustumite occurs

98 together with defernite, dellaite, spurrite, vesuvianite, hydrogrossular, foshagite and killalaite  
99 (Figure 1a).

100 F-bearing rustumite (Rust2\_F) with Cl content close to end-member occurs at the contact  
101 between xenolith no.1 (Galuskin et al. 2009) and unaltered ignimbrites of the Upper Chegem  
102 Caldera, Northern Caucasus, Russia. Lens like rustumite-aggregates are surrounded by a  
103 bultfonteinite matrix (Figure 1b). In addition, at the contact to the ignimbrite wollastonite and  
104 rustumite form a thin transition zone. The rocks represent altered larnite exoskarns composed of  
105 cuspidine, hillebrandite, lakargiite, wadalite.

106 Rust3\_LCl\_F, a F-bearing, low-Cl rustumite forms symplectites together with  
107 monticellite replacing merwinite skarn of the Birkhin massif, Baikal Lake area, Eastern Siberia;  
108 Russia. A summary of the geological setting is reported by Lazic et al. (2011). Within the  
109 symplectite, clusters of clintonite and vesuvianite are observed (Figure 1c,d). In addition, larnite,  
110 merwinite, melilite, cuspidine, spurrite, bredigite, magnetite, perovskite, andradite and kerimasite  
111 occur in minor concentrations.

## 112 **Experimental**

113

114 Chemical analyses were carried out using an electron microprobe CAMECA SX100,  
115 (WDS mode, 15 kV, 10-20 nA, 1-3  $\mu\text{m}$  beam diameter). Natural and synthetic standards were  
116 employed. The following lines and standards were used for rustumite analyses: CaK $\alpha$ , SiK $\alpha$  –  
117 wollastonite; FeK $\alpha$  – hematite, TiK $\alpha$  – rutile, MnK $\alpha$  – rhodochrosite; MgK $\alpha$  – diopside; NaK $\alpha$  –  
118 albite, AlK $\alpha$  – orthoclase, SK $\alpha$  – barite, FK $\alpha$  – fluorphlogopite, ClK $\alpha$  – tugtupite. For the sample  
119 Rust3\_LCl\_F from Birkhin the same crystals as used for structure refinement were analyzed with  
120 the electron-microprobe. For the other samples, analytical data were collected from crystals of the  
121 same thin section, from which also the structurally investigated crystals were extracted.

122 Raman spectra of all samples were recorded using a Dilor XY spectrometer equipped with  
123 a 1800 line  $\text{mm}^{-1}$  grating monochromator, a charge-coupled device (CCD), Peltier-cooled  
124 detector (1024 $\times$ 256) and an Olympus BX40 confocal microscope. The incident laser excitation  
125 was provided by a water-cooled argon laser source operating at 514.5 nm. The power at the exit  
126 of a 100x objective lens varied from 30 to 50 mW. Raman spectra were recorded in  
127 backscattering geometry in the range 100-4000  $\text{cm}^{-1}$  with resolution of 2  $\text{cm}^{-1}$ . Collection times of

128 20 s and accumulation of 5 scans were chosen. The monochromator was calibrated using the  
129 Raman scattering line of a silicon plate ( $520.7 \text{ cm}^{-1}$ ).

130 Single-crystal X-ray studies were carried out on three samples of rustumite low-Cl  
131 rustumite from Rize-batholite near Ikizdere (Rust1\_LCl), F-bearing rustumite from the Chegem  
132 Caldera (Rust2\_F), (Northern Caucasus) and low-Cl, F-bearing rustumite from Birkhin massif  
133 (Rust3\_LCl\_F), using a Bruker APEX II SMART diffractometer ( $\text{MoK}\alpha$ ,  $\lambda = 0.71073 \text{ \AA}$ ).  
134 Experimental details are summarized in Table 1. Diffraction data were collected with  $\omega$  scans at  
135 different  $\varphi$  settings ( $\varphi$ - $\omega$  scan) (Bruker, 1999). Data were processed using SAINT (Bruker, 1999).  
136 An empirical absorption correction using SADABS (Sheldrick, 1996) was applied. The structure  
137 was solved by direct methods with subsequent analyses of difference-Fourier maps. The  
138 rustumite structures were refined using the program SHELX97 (Sheldrick, 2008) to  $R1 = 2.05\%$   
139 (Rust1\_LCl),  $R1 = 2.95\%$  (Rust2\_F) and  $2.43 \%$  (Rust3\_LCl\_F). The refinements including  
140 anisotropic atom displacement-parameters (except for H) have been carried out with neutral atom  
141 scattering-factors. If splitting of the Cl1 site was observed, two positions with common  
142 anisotropic displacement parameters were refined. The position with the longer distances to Ca  
143 was considered Cl and the one with the shorter distances was interpreted as O (OH). The  
144 occupancy of both sites were determined with the restraint  $\text{OH} + \text{Cl} = 1$ . Positions of the  
145 hydroxyl-group hydrogen atoms were derived from difference-Fourier syntheses. Subsequently,  
146 hydrogen positions were refined with restrained O-H distances of  $0.96(2) \text{ \AA}$ . For Rust2\_F no H-  
147 position has been refined, but a peak of 0.47 electrons near the predicted H2 site was observed in  
148 the difference Fourier-map. After standard refinement of the structure of rustumite from Birkhin  
149 (Rust3\_LCl\_F) we became aware of several inconsistencies compared to the previously refined  
150 rustumite samples: (1) residual density-of about 2 electrons close to Ca2 suggested splitting of  
151 Ca2 into two subsites (Ca2 and Ca2A). (2) The mean  $\langle \text{Si3-O} \rangle$  bond length within the  
152 orthosilicate group became  $1.67 \text{ \AA}$  and was ca.  $0.02 \text{ \AA}$  longer compared to the other samples. (3)  
153 The displacement parameter  $U_{\text{eq}}$  of Si3 was a factor of two larger than those of Si1 and Si2. In the  
154 other investigated samples displacement parameters of the three Si sites were similar to each  
155 other. (4) There was low residual density in difference-Fourier maps close to O4 and O8 (refined  
156 as subsites), which are the oxygen sites coordinating Si3. These findings (1-4) were interpreted  
157 with partial Si3 vacancies as known for a hydrogarnet-like substitution (Lager et al. 1987,  
158 Galuskin et al., 2007) or as a fluorine substitution at the subsites O4A and O8A . If the Si site is

159 empty the tetrahedron expands with  $2 \times \text{O4A}$  and  $2 \times \text{O8A}$  as tetrahedral apices. The splitting of  
160 original O4 into O4 and O4A also required splitting of Ca2 bonded to O4 and O4A. As a  
161 consequence of the hydrogarnet-type or F-substitution at the orthosilicate site, the occupancies of  
162 Si3, O4, O4A, O8, O8A, Ca2 and Ca2A were constrained to each other and refined with one  
163 variable. Subsequent refinements converged to Si3 occupancy of 0.876(4). We actually measured  
164 and refined structures of four rustumite crystals from Birkhin and all showed similar degree of  
165 hydrogarnet-like substitution.

166 The structure of rustumite possesses an alternative setting in space group  $C2/c$  with  
167 similar unit cell dimensions ( $a = 7.59$ ,  $b = 18.58$ ,  $c = 15.43 \text{ \AA}$   $\beta = 103.82^\circ$ ). This second setting  
168 may be obtained from our setting ( $a = 7.59$ ,  $b = 18.58$ ,  $c = 15.49 \text{ \AA}$   $\beta = 104.60^\circ$ ) by the  
169 transformation matrix  $(1 \ 0 \ 0, 0 \ -1 \ 0, -1 \ 0 \ -1)$ . Due to the strong similarity in cell dimensions in  
170 both settings, pseudo-merohedral twinning according to the above matrix is common in  
171 rustumite. Corresponding twin refinements  $(1 \ 0 \ 0, 0 \ -1 \ 0, -1 \ 0 \ -1)$  converged to following  
172 fractions of twin individuals: 0.536(15) for Rust2\_F and 0.005(5) for Rust3\_LCl\_F, respectively.  
173 The lower accuracy of cell dimensions for sample Rust2\_F compared to the other studied  
174 rustumites is due to this pseudo-merohedral twinning.

## 175 **Results**

176 The electron-microprobe data is listed in Table 2. Variable Cl, F and OH contents are  
177 striking. The results for single-crystal structure refinement are summarised in Table 1, atomic  
178 coordinates and isotropic equivalents ( $U_{eq}$ ) of anisotropic atom-displacement parameters in  
179 Tables 3 a-c, anisotropic atomic-displacement parameters in Tables 4 a-c (deposited material) and  
180 selected interatomic distances in Table 5. The results for hydrogen bond distances and angles are  
181 listed in Table 6 a-c. Raman spectra for the three rustumite samples are displayed in Figure 2.  
182 The shape of the general pattern between  $1200 - 100 \text{ cm}^{-1}$  is similar for all. Major differences are  
183 observed in the region of OH-vibrations. Rust1\_LCl shows two strong bands at  $3632 \text{ cm}^{-1}$  and  
184  $3598 \text{ cm}^{-1}$ . The latter is shifted towards lower wavenumbers at  $3585 \text{ cm}^{-1}$  in the case of Rust2\_F.  
185 Only one strong band at the same position is observed for the sample Rust3\_LCl\_F.

186

## 187 **Discussion**

188         The results of our experiments confirm the correctness of the assumptions by Howie and  
189 Ilyukhin (1977) interpreting the increased electron density at the O10 site to be caused by Cl (Fig.  
190 3). However, complete occupancy of this site by Cl is rather the exception than the rule (e.g.,  
191 Kanazawa et al. 1997; Hezarkhani 2006; this study). Moreover, O11 was assumed (Howie and  
192 Ilyukhin 1977) to be OH, which is consistent with our results if we allow for substitution by F. In  
193 the present study the sites O10 and O11 (Howie and Ilyukhin 1977) have been relabelled to  
194 Cl1/OH1 and OH2/F, respectively. Cl1/OH1 is fivefold coordinated by Ca1,  $2 \times$  Ca2 and  $2 \times$  Ca3  
195 building a square based pyramid. OH2/F is only threefold coordinated by Ca3, Ca4 and Ca5 and  
196 is adjacent to its symmetry equivalent OH2/F' (-x, y, -z +1/2). The three examined samples show  
197 variable content of monovalent anions Cl, F, OH occupying these two sites. In general depletion  
198 in Cl is reflected in shortening of the *a* axis and decrease of cell volume.

199         Sample Rust1\_LCl (Turkey) is depleted in Cl (1.284 Cl pfu) compared to the ideal  
200 formula (Table 2). The OH2/F site is almost fully occupied by OH with minor F, while Cl1/OH1  
201 hosts OH and Cl. The occupancy for Cl1 converged to 0.67 (Table 3a) which is consistent with  
202 the chemical analysis. OH2 and its symmetry equivalent OH2' are separated by 3.119(3) Å and  
203 are potential hydrogen bond donors and acceptors for each other. Since only one can act as an  
204 acceptor, otherwise two adjacent H sites are too close-by, two alternative hydrogen positions are  
205 present. H2b points towards OH2 leading to a hydrogen bond OH2-H2b...OH2' with a  
206 H2b...OH2'-distance of 2.19(3) Å and an OH2-H2b-OH2' angle of 154(5)° (Fig. 4). H2a points  
207 towards the anion at the Cl1/OH1 site, acting as acceptor. The distance H2a...Cl1/OH1 is 2.43(4)  
208 Å and the angle OH2-H2a-Cl1 is 141(5)° (Table 6). This indicates weaker bonding compared to  
209 OH2-H2b...OH2' (Figure 4a). The hydrogen position of OH-groups at the Cl1/OH1 site has only  
210 been derived for Rust3\_LCl\_F and points towards OH2/F (Figure 4c).

211         In sample Rust2\_F (Caucasus) the Cl1/OH1 site is almost fully occupied by Cl. F and  
212 OH-groups share the OH2/F site. Regarding to hydrogen bonding, substitution of every second  
213 OH2/F site by F is favorable compared to OH-groups adjacent to each other (Figure 4b).

214         Sample Rust3\_LCl\_F (Baikal) shows severe depletion in Cl (1.00 atoms pfu) as well as  
215 high F content (0.987 atoms pfu) (Table 2). Similar to Rust2\_F, OH2/F is shared by OH and F.  
216 The distance H2...F is 2.13(4) Å with an OH2-H2-F angle of 155(6)° (Table 6). The sum of the  
217 bond valences after Brown and Altermatt (1985) for F on OH2/F results in 0.78 vu. Thus F has  
218 high hydrogen-bond acceptor capacity. Cl1/OH1 hosts Cl and OH-groups similar to Rust1\_LCl.

219 The hydrogen position H1 is at the back of the square-based pyramid centered by OH1/Cl1. H1  
220 has the two anions at the OH2/F site as potential hydrogen bond acceptors. Our results can not  
221 rule out partial occupation of the OH1/Cl1-site by F but the arrangement of OH2/F and OH2/F'  
222 gives rise to the following prediction. Assuming an ordered situation with F on each second  
223 OH2/F site, and OH on each second OH1/Cl1 site, two possible situations result. Either H1 has  
224 OH2 as hydrogen-bond acceptor or F (Figure 4 c1 and c2). Since F is strongly underbonded, F as  
225 acceptor is most likely. The donor-acceptor distance is 3.398(10) Å and the hydrogen-bond  
226 length H1...OH2/F is 2.65(4) Å with an OH1-H1-OH2/F angle of 136(4)° (Table 6). Unique for  
227 Rust3\_LCl\_F is the partial occupation (0.88) of the Si3 site, which is interpreted as a  
228 hydrogarnet-type substitution  $\text{SiO}_4 = (\text{OH})_4$  (Lager et al. 1987; Galuskin et al. 2007). In the case  
229 of empty Si3 tetrahedra, O4 and O8, representing tetrahedral apices of Si3, are no longer attracted  
230 by a cationic charge in the tetrahedron center and the subsites (O4A and O8A) have elongate  
231 distances to the tetrahedron center. O4A is shifted towards the triangle Ca4, Ca5 and Ca2. The  
232 proximity of O4A to Ca2 causes displacement of Ca2 to Ca2A whenever O4A is occupied. In our  
233 model with split Ca2 (Ca2 and Ca2A) O4A bonds to Ca2A and O4 to Ca2. O8A is shifted  
234 towards Ca5, Ca4 and Ca1. The hydrogarnet-like substitution produces two similar tetrahedra  
235 next to Cl: (1) with O4A, O8A and 2 × OH2 as apices, (2) with 2 × O4A and 2 × O8A as apices  
236 (Figure 5). Instead of hydrogarnet-type substitution, the splitting of the O4 and O8 sites may also  
237 be explained by the occupation of O4A and O8A by F. However, the present data do not allow  
238 excluding neither one of these possibilities nor a combination of both.

239 In accordance with our X-ray experiments, the major differences in the three Raman  
240 spectra are observed in the region of OH-stretching modes. Strong bands are present in a narrow  
241 range between 3650 cm<sup>-1</sup> and 3540 cm<sup>-1</sup> all representing weak hydrogen bonds (Libowitzky  
242 1999). In the range of donor-acceptor distances around 3Å the Raman-wavenumbers are closely  
243 spaced which complicates the interpretation. Furthermore, one should take into account that F  
244 and Cl have not been considered by Libowitzky (1999) as hydrogen-bond acceptors.

245 Both F-bearing rustumites show a strong band at 3584 cm<sup>-1</sup>, which is assigned to OH2-  
246 H2...F. The band at 3632 cm<sup>-1</sup> is observed for F-bearing rustumite and low-Cl rustumite and is  
247 interpreted to display the weak interaction between OH2-H2a and Cl1. Low-chlorine rustumite  
248 shows another strong band at 3598 cm<sup>-1</sup>, which is most likely due to the interaction of OH2-  
249 H2...OH2. Since the fluorine content for F-bearing rustumite is not enough to occupy each  
250 second OH2/F site (< 1 F pfu) this band is also expected for F-bearing rustumite but has not been

251 observed. The shoulder at  $3645\text{ cm}^{-1}$ , observed for low-Cl rustumite, may be caused by the long  
252 hydrogen bond  $\text{OH1-H1}\cdots\text{OH2/F}$ . But this band is not observed for Rust3\_LCl\_F. Assuming a H-  
253 setting for the hydrogarnet-type substitution according to Lager et al. (1987) we would expect  
254 Raman-bands at higher wavenumbers which are not resolved. Although the interpretation of the  
255 Raman spectra is certainly ambiguous a slight strengthening of the hydrogen bond system due to  
256 fluorine uptake is observed. The depletion in chlorine is not obviously displayed in the Raman-  
257 spectra.

258 None of the hitherto reported chemical compositions of rustumite reaches the ideal  
259 chlorine content of 2 apfu, although rustumite from Northern Caucasus, studied in this paper, has  
260 1.96 Cl pfu. Low-Cl rustumite and Cl-bearing dellaite may not be distinguished by electron  
261 microprobe analysis since they share the same Ca/Si ratio and variable Cl content (Armbruster et  
262 al. 2011). As rustumite and dellaite grow within the same mineral association (Agrell 1965, this  
263 study) the question about the formation conditions arises. A paragenesis of two Ca-silicates with  
264 the same Ca/Si ratio and similar chlorine content is rather unlikely. In sample Rust3\_LCl\_F  
265 (Birkhin massif) (Figure 1 c,d) replacement of dellaite by rustumite is observed along a system of  
266 cracks and micro-veins, crosscutting the preexisting dellaite-monticellite symplectites. Two  
267 reaction-series may be distinguished: (1) Dellaite – Cl-bearing dellaite – rustumite and (2)  
268 dellaite – cuspidine – rustumite + F-bearing spurrite.

269

## 270 **Acknowledgement**

271 We highly appreciate the constructive evaluations of two anonymous reviewers. T.A. and B.L.  
272 acknowledge support by the Swiss National Science Foundation project “Crystal Chemistry of  
273 Minerals” 200020\_134617. We acknowledge receiving rustumite reference samples NMNH  
274 119428, Smithsonian Institution, Washington, D.C. and M35011 Museum Victoria, Melbourne.

368 Figure 1. (a) Back scattered electron (BSE) image of low-Cl rustumite from the Rize-batholite near  
369 Ikizdere, Eastern Turkey (Rust1\_LCl). A big rustumite (Rst) grain with hydrogrossular (Hgr) inclusion is  
370 associated with defernite (Dfr), vesuvianite (Ves), dellaite (Del), spurrite (Spu), foshagite (Fsh), and  
371 killalaite (Kil). (b) BSE-image of rustumite from the Upper Chegem Caldera, Northern Caucasus  
372 (Rust2\_F). Rustumite forms lens like aggregates within a bultfonteinite (Blt) matrix. (c) Transmitted light  
373 image of low-Cl, F-bearing rustumite (Rust3\_LCl\_F) with crossed polarizers. Rustumite builds  
374 symplectites with monticellite (Mtc) and additional magnetite (Mgt), aggregates of clintonite (Cln) and  
375 vesuvianite. (d) Back scattered electron image of the white framed area in (c).

376

377 Figure 2. Raman spectra for Rust2\_F (Caucasus) (1), Rust1\_LCl (Turkey) (2) and Rust3\_LCl\_F (Baikal)  
378 (3).

379

380 Figure 3. The crystal structure of rustumite projected along the **a**-axis. Thin solid lines are unit cell  
381 outlines. Disilicate units are shown as red and orthosilicate units as rose tetrahedra. Disilicate units extend  
382 along **a**. Calcium atoms are displayed as yellow, oxygen as small purple, and Cl as green spheres. The  
383 black frame marks (thick solid lines) the area of the close-up in Figure 4.

384

385 Figure 4. Perspective view of hydrogen bond systems for (a) low-chlorine rustumite (Rust1\_LCl) (b) F-  
386 bearing rustumite Rust2\_F and (c1,c2) F-bearing, low-chlorine rustumite (Rust\_3\_LCl\_F). Hydrogen  
387 bonds are drawn as striped cylinders. The cake diagrams display the relative amounts of monovalent  
388 anions partitioned to Cl1/OH1 left and OH2/F right. In (a) two hydrogen bonds are distinguished. H2a  
389 interacts with Cl1, H2b with OH2 as acceptor. For F-bearing rustumite (b) the hydrogen position points  
390 towards OH2/F. In (c) two Cl1/OH1 sites are displayed. The one in the front occupied by OH the one  
391 behind by Cl. One of the two OH2/F sites is occupied by F, which is acceptor of the hydrogen bond from  
392 H2. The hydrogen position of OH1 points towards OH2/F where it either interacts with F (c1) or OH2  
393 (c2).

394

395 Figure 5. Detailed view of the Si3 site in Rust3\_LCl\_F projected along the **b**-axis with (a) and without (b)  
396 hydrogarnet-like substitution. Due to the lack of cationic charge O8 and O4 shift away from the former  
397 orthosilicate site and build two similar tetrahedra (O8A 2x OH2 2x as apices left and 2x O8A and 2x O4A  
398 as apices right). The proximity of O4A to Ca2 causes displacement of Ca2 to Ca2A whenever  
399 O4A is occupied. The green spheres represent Cl.
