## ABSTRACT

Lakebogaite, ideally  $CaNaFe_2^{3+}H(UO_2)_2(PO_4)_4(OH)_2(H_2O)_8$ , is a new Ca–Na–Fe uranyl phosphate mineral from a quarry in Upper Devonian granite near Lake Boga, northern Victoria, Australia. It is associated with Na-analogue of meurigite (IMA 2007-024), torbernite, and saléeite on a matrix of microcline, albite, smoky quartz, and muscovite. Lakebogaite occurs as bright lemon-yellow transparent prismatic crystals up to 0.4 mm across. The crystals have a vitreous luster and a pale yellow streak. Mohs hardness is about 3. The fracture is even to conchoidal. In transmitted light, the mineral is pale yellow with very weak pleochroism: X = yellow, Y = gravish yellow, Z = gravish yellow: dispersion r > v, strong. Lakebogaite crystals are biaxial (+), with slightly variable refractive indices within the ranges:  $n_{\alpha} = 1.650(2) - 1.652(2)$ ,  $n_{\beta} = 1.660(4) - 1.664(3)$ ,  $n_{\gamma} = 1.681(3) - 1.686(2)$ , measured using white light, and with  $2V_{\text{meas}} = 80-85^{\circ}$  and  $2V_{\text{calc}} = 70-74^{\circ}$ . Orientation: Y = b; crystals are elongated along [010], resulting in straight extinction. The empirical chemical formula (mean of nine electron microprobe analyses) calculated on the basis of 30 anions is  $(Ca_{1,00}Na_{0,80}Sr_{0,10})_{\Sigma_{1,00}}(Fe_{1,85}^{3+}Al_{0,30})_{\Sigma_{1,0}}(UO_2)_{1,80}$  $(PO_4)_{4.07}(OH, H_2O)_{10.12}$ . Lakebogaite is monoclinic, space group Cc, a = 19.6441(5), b = 7.0958(2), cc = 18.7029(5) Å,  $\beta = 115.692(1)^{\circ}$ , V = 2349.3(7) Å<sup>3</sup>, Z = 4. The seven strongest reflections in the powder X-ray diffraction pattern are  $[d_{obs} \text{ in } \text{\AA}(I) (hkl)]$ : 6.60 (100) (110), 3.16 (40) (51 $\overline{4}$ , 60 $\overline{4}$ ), 4.07  $(20)(40\overline{4}), 3.80(20)(31\overline{4}), 3.56(20)(020, 312), 3.31(20)(114, 220), 2.797(20)(006)$ . The crystal structure was solved from single-crystal X-ray diffraction data and refined to  $R_1 = 0.038$  on the basis of 5222 unique reflections with  $F > 4\sigma F$ . It comprises pairs of edge-shared UO<sub>7</sub> pentagonal bipyramids that are inter-linked via corner-sharing with PO<sub>4</sub> tetrahedra, to form chains parallel to the **c**-axis. Each UO<sub>7</sub> polyhedron also shares one of its edges with another PO<sub>4</sub> tetrahedron. The  $(UO_2)_2(PO_4)_4$ chains are cross-linked via corner-sharing between the  $PO_4$  tetrahedra and  $Fe^{3+}O_4(OH)_2$  octahedra. The octahedra join together by corner-sharing via OH anions to form chains parallel to  $\mathbf{b}$ . The Na<sup>+</sup> and  $Ca^{2+}$  cations, and 4 water molecules occupy eight-sided channels along [010]. The remaining water molecules occupy large ten-sided channels directed along [001] and intersecting the [010] channels. The mineral is named for the nearest township.
