NEW MINERAL NAMES

Karrenbergeite

A preliminary description. Analysis gave SiO$_2$ 40.90, Al$_2$O$_3$ 5.25, Fe$_3$O$_4$ 14.43, FeO 8.24, MgO 4.37, CaO 1.73, Na$_2$O 0.81, K$_2$O 0.20, H$_2$O 18.42, ign. loss 6.18, sum 100.53 per cent. This is calculated to the montmorillonite-type formula (Mg$_{0.3}Fe^{\text{II}}_{0.5}Fe^{\text{III}}_{0.2}Al_{0.3})_2(Si_{0.6}Al_{0.4})_2Ca_{0.6}Na_{0.4}K_{0.4} \cdot H_2O_6$\_$_2$, intermediate between nontronite and saponite.

X-ray powder data are 15.23 vs, 4.57 m, 3 05 w, broad, 2.06 m, broad, 1.53 m. Indices of refraction: $\alpha$ 1.510, $\gamma$ 1.528, X brownish-yellow, Z dark olive-green. Fibrous, greenish-brown, transparent.

The mineral occurs in a geode in hyalo-dacite on scalenohedral calcite that is partly replaced by chalcedony and is associated with yellow transparent opal and yellow fibrous cristobalite (lussatite). It is covered by fine reddish natrolite. The occurrence is in the Karrenberg, near Reichweiler, Pfalz.

The name is for the locality.

Norsethite

The mineral occurs as clear to milky white circular plates or flattened rhombohedral crystals 0.2-2 mm. across. Forms observed: $c\{001\}$, $a\{1120\}$, $m\{10\}$. Probably space group $R32-D_32$, $a_{n}6.29$, $a_{n}37^\circ$, $Z=1$ in the rhombohedral cell.

The strongest X-ray lines are 3.015 (100), 3.860 (35), 2.656 (35), 2.512 (35), 2.104 (35), 1.931 (35), 1.864 (35), 1.351 (35), 1.240 (35). Cleavage rhombohedral good, fracture hackly. Analysis made on 0.1 g. gave BaO 52.9, CaO 0.5, MnO 0.1, MgO 13.9, Fe$_3$O$_4$ (total Fe) 0.4, CO$_2$ 31.2, SiO$_2$ 0.3, insol. 0.5, total 99.8%. Insoluble. Insoluble in water, decomposed by cold dilute HCl.

Luster vitreous to pearly, H. 3+, G. 3.837 (measured), 3.84 (calcld.). Optically uniaxial, negative $\alpha$ 1.694, $\epsilon$ 1.519.

Norseithite occurs in black dolomitic oil shale below the main trona bed in the Westvaco trona mine, Sweetwater County, Wyoming, associated with shortite, labuntsovite, searlesite, loughlinite, pyrite, and quartz. It also occurs in similar association and with northupite in gray shale.

The name is for Keith Norseth, geologist of the Westvaco trona mine.

Fenaksite

Analyses of two samples from the same pegmatite (by A. V. M. and Z. I. G., resp.) gave SiO$_2$ 60.14, 60.54; TiO$_2$ 0.06, 0.04; Al$_2$O$_3$ 1.10, 0.66; Fe$_2$O$_3$ 1.32, 1.54; FeO 12.45, 12.49; MgO 0.46, 0.70; MnO 2.34, 2.49; CaO 0.64, 0.74; Na$_2$O 6.77, 7.51; K$_2$O 11.48, 11.71; H$_2$O$_2$ 0.76, 0.78; H$_4$O$_2$ 2.40, 0.67; F 0.23, 0.47, sum 100.15, 100.34. $D = 10.00$, $D = 100.00$, 100.14%. Determinations on a third sample gave H$_2$O$_2$ 1.12, H$_2$O$_2$ 0.91%. Spectrographic analysis by N. N. Kolesnikov showed, in addition to the elements listed Ba—trace, Cu,
Zr, Sr—faint lines. After subtraction of a small amount of adularia (calculated from Al₂O₃), these analyses correspond to the formula (K, Na)₅(Fe²⁺, Mn)₂(SiO₄)₅(OH, F) with K:Na nearly 1:1. Fenaksite is decomposed by acids with the deposition of silica. It fuses easily before the blowpipe to a green glass; in the reducing flame, the powder becomes magnetic. From the composition, it may be referred either to the apophyllite group or to the mica group.

The mineral occurs in grains up to 2–4 cm in diameter.

It is light rose in color, luster pearly on the two cleavages, which are at an angle of 122° to one another. Hardness 5–5½. G. 2.744 (pycnometer). It is optically biaxial, positive; ns (Na) α 1.541, β 1.500, γ 1.567, 2V 84°, Z = b, plane of optic axes (001), Z: cleavage I = 20°, Y: cleavage II = 49°, X: cleavage II = 8°.

Laue and rotation photographs show the mineral to be monoclinic, space group C 2/m, C2, or Cm, α₀ 14.95, b₀ 6.98, c₀ 9.79 (not stated whether A or kX), β 112°, Z = 2. X-ray powder data by N. N. Sludsko are given: the strongest lines are 3.03 (10), 2.46 (7), doublet 3.55, 3.44 (7), 2.88 (6), 2.71 (6), 1.875, 1.835 (5), 1.752 (6).

The name is for the composition.

Discussion.—There must be an error in the optical data; the indices of refraction given indicate an optically negative mineral with 2V 61°. Perhaps β should be 1.550, which would give 2V 74°?

The name is unfortunate because it is so easily confused with phenakite. This may be the Mineral No. 5 of Dorfman (see Am. Mineral. 44, 910 (1959)).

M. F.

Canasite

Chemical analyses of two samples from the same pegmatite, by E. I. U. and Z. I. G., respectively, gave SiO₂ 56.08, 55.71; TiO₂ 0.10, 0.06; Al₂O₃ 0.55, 0.20; Fe₂O₃ 1.41, 0.72; FeO 0.71, 0.36; MgO 0.05, 0.26; MnO 0.38, 0.41; CaO 20.95, 20.39; Na₂O 8.01, 7.08; K₂O 8.47, 10.63; H₂O 0.49, 0.60; H₂O 0.11, 1.25, F 2.21, 2.17; Cl 0.22, —; CO₂ 0.20, —; P₂O₅ 0.04, 0.08; sum. 100.98, 99.92 — (0: F) 0.96, 0.91 = 100.02, 99.91%.

A footnote to the first analysis states that “the determination of Na provokes doubts.” Spectrographic analysis shows, in addition to the elements listed above, Sr—medium, Ni, Cu—weak, Be—insignificant traces. After deducting small amounts of magnetite (calculated from Fe₂O₃) and adularia (calculated from Al₂O₃), these analyses give the formula: (Na, K)₅ Ca₂ (SiO₄)₅(OH, F)₃. The mineral is decomposed by acids with the separation of silica. Easily fusible to a transparent glass in the blowpipe or alcohol flame.

Canasite occurs in grains up to 3 cm in diameter. Transparent and translucent, color greenish-yellow, streak colorless. Luster vitreous. The mineral has a perfect cleavage and a very perfect cleavage at an angle of 118° to the first. Brittle, fracture splintery, breaks into long acute-angled or wedge-shaped pieces. When ground, gives a fealty mass. G. (pycnometer) 2.707.

The mineral is optically biaxial, negative; ns (Na) α 1.534, β 1.538, γ 1.543, 2V 58°. The optic axial plane is (010), Y = b, Z: less perfect cleavage = 2°. Polysynthetic twinning was observed, with the twinning plane at an angle of 8° to the less perfect cleavage.

Laue, rotation, and DeJong photographs showed canasite to be monoclinic, space group C2/m, C2, or Cm, α₀ 18.87, b₀ 7.24, c₀ 12.60, β 112°. Unindexed x-ray powder data are given; the strongest lines are 3.074 (broad) — 10, 1.814 — 9, 2.901 — 8, 1.638 — 8, 4.68 — 7, 4.80 — 6, 2.354 — 6.
The mineral occurs with fenaksite (see preceding abstract). Lamprophyllite occurs in fractures in canasite. The name is for the chemical composition.

DISCUSSION.—Presumably to be classed as a phyllosilicate. This may be Mineral No. 6 of Dorfman (see Am. Mineral. 44, 910 (1959). The indices of refraction given do not correspond to the figure given for 2V.

M. F.

**Metakahlerite**

The mineral was found as sulfur-yellow rare scaly aggregates in the Sophia Shaft, Baden. Microchemical tests showed Fe, U, As. Composition presumably Fe (UO₂)₂ (AsO₃)₂·8H₂O. Cleavage (001) excellent, (100) good. Luster pearly on (001). Optically uniaxial to biaxial, negative with 2V up to 22°, nₑ 1.608, n₆ 1.642, both ±0.002, weakly pleochroic, E nearly colorless, O pale yellow. Not fluorescent. The x-ray powder diagram indicates this to be a meta-form; the strongest lines are 3.59 (10), 8.55 (9), 4.29 (6), 5.11 (5), 2.15 (5), 2.11 (5).

M. F.

**Meta-uranospinite**

Name given to the dehydration product of uranospinite from the Clara shaft, Wüften, Baden, characterized by higher indices of refraction than uranospinite, nₑ 1.618. Weakly pleochroic, X colorless, Z pale yellow. Readily rehydrates to uranospinite. Formula presumably Ca (UO₂)₂ (AsO₃)₂·8H₂O.

M. F.

**Unnamed Ca, Sr, U oxides**

Pseudo-hexagonal reddish-orange crystals, up to 0.5 mm., were found in geodes and in fissures in gummite on altered pitchblende from the Margnac II Mine. Microchemical tests and spectrographic analysis showed Ca, Sr, and U. Analysis gave UO₃ 83.9, H₂O 7.4%. Phosphate, sulfate, carbonate, and silicate were absent. The crystals showed (001) (dominant), (010), (110), (111), and rarely (101). G·5.29±0.05. Orthorhombic with a₀ 15.46±0.05, b₀ 74.12±0.10, c₀ 14.16±0.10 Å. Cleavage (001) good. Biaxial, negative, β 1.94, γ 1.96, 2V 38±3°. The x-ray powder pattern has strongest lines 3.11 (vs), 3.47 (s-vs), 6.82 (s), 3.53 (s), 3.17 (ms), 1.966 (ms).

When the mineral is heated in water at 100°, it is transformed into material giving a powder pattern identical with that given by pale yellow spherulites associated with the orange mineral. The strongest lines are 7.09 (vs), 3.49 (s), 3.13 (s), 1.951 (ms).

M. F.

**Unnamed ("Mineral X")**

An unknown fibrous mineral associated with wiserite (see page 256) gave x-ray powder data and fiber diagrams that were indexed on a monoclinic cell with a₀ 11.55±0.05,
NEW MINERAL NAMES

$\beta_0 3.4 \pm 0.3$, $c_0 8.18 \pm 0.05$ kX, $\beta 109.5^\circ$. The fiber axis is parallel to $b$. The strongest lines are (in kX) 10.75 s, 5.4 s, 3.68 s, 2.93 s, 1.791 s. Optical data were uncertain because of intergrowth with wiserite; $\alpha$ ranged from 1.690–1.710, $\gamma$ was about 1.76. Extinction inclined, up to 5°. Spectrographic analyses of mixtures with wiserite showed the same elements as in wiserite, so the mineral is probably a manganese borate.

M. F.

Unnamed

The mineral occurs in clefts between barite layers and calcium silicate rock in the Candoglia marble, associated with barite, barium feldspar, quartz, epidote, and calcite. It forms bright gray columns up to 5 cm. long and 1 cm. thick. Luster vitreous to pearly, somewhat greasy on fractures. Brittle, H. = 6. G. (pycnometer) 3.13. Cleavage prismatic, parting pinacoidal. Optically uniaxial to biaxial, negative, 2V 0–10°, $n_s$ 1.595, $n_e$ 1.589.

Analysis by H. Schwander of material picked under the binoculars gave SiO$_2$ 31.5, Al$_2$O$_3$ 19.5, CaO 12.0, BaO 23.5, Na$_2$O 0.6, K$_2$O 0.8, SO$_3$ 9.9, H$_2$O 2.4, Cl tr., sum 100.2%. This gives 5BaO · 8CaO · 7Al$_2$O$_3$ · 19SiO$_2$ · 4SO$_3$ · 5H$_2$O (Recalculation gives $Na_2O$, $K_2O$, $BaO$, $CaO$, $SiO_2$, $SO_3$, $H_2O$, $M.F.$). The SO$_3$ would correspond to 29.2% barite, but microscopic and x-ray study, which showed only faint lines of barite, indicated that no more than 5% barite could be present. The mineral may be related to scapolite, but the indices of refraction are low for the high content of BaO.

M. F.

Dixeyite

The mineral was found in a small outcrop of amphibolite 1 mile north of the village of Bellahun, Kangari Hills, central Sierra Leone. The amphibolite is believed to occupy a very narrow zone along the margin of ultrabasic rock at its contact with granodiorite. The rock consists of hornblende, quartz, magnetite, and an unknown isotropic colorless mineral; a chemical analysis, but no mode, of the rock is given. Separation by heavy liquid gave a concentrate “Predominantly containing the unknown isotropic mineral.” Analysis of this concentrate by Aulis Heikinnen gave SiO$_2$ 51.72, TiO$_2$ 0.55, Al$_2$O$_3$ 21.15, FeO 2.68, FeO 2.76, MnO 0.15, MgO 2.17, CaO 2.56, Na$_2$O 0.34, K$_2$O 0.32, P$_2$O$_5$ 0.45, CO$_2$ none, H$_2$O+10.26, H$_2$O–5.03, sum 100.14%. From this, an unstated amount of hornblende and magnetite is deducted, leaving (in moles) SiO$_2$ 730, Al$_2$O$_3$ 166, K$_2$O 3.5, CaO 2, H$_2$O 570, or approximately Al$_2$O$_3$ 4–5 SiO$_2$ 3–4 H$_2$O. Some quartz was present. Analysis of “a few mg. of reasonably pure material” gave SiO$_2$ 63.14, Al$_2$O$_3$ 23.65, Fe traces, CaO 0.05%, confirming the above formula. (Al$_2$O$_3$/SiO$_2$ = 1:4.5.)

X-ray powder data showed some variation; 2 patterns gave $a_0$ 7.55, 7.7 Å; “this suggests that the lattice may not be exactly cubic.” Calculations gives 22.55 O atoms per unit cell, which suggests that $a_0$ should be doubled to 15.2 Å. The strongest x-ray lines are 3.32, 3.40 (s), 3.09, 3.19 (s), 2.27 (s). G. approximately 2.51–2.52, $n$ 1.5057. The mineral is perfectly isotropic.

The name is for F. Dixey, Director, British Overseas Geological Surveys, first government geologist of Sierra Leone.

DISCUSSION.—An unsatisfactory description.

M. F.
Dneprovskite

The name was proposed in 1944 by P. I. Skornyakov for wood tin of radiating fibrous structure from the Dnepropetrovsk deposits, northeastern U.S.S.R.

Discussion.—As the abstractor states, an unnecessary name.

Khovakhsite, Tuvite

These are names used in the literature of economic geology for oxidation products of smaltite and safflorite. Khovakhsite is light to dark brown, earthy, luster waxy or resinous, H. 2½-3, G. 2.81. The composition ranges from Fe₂O₃·2(Ca, Co)O·As₂O₅·3-6H₂O to Fe₂O₃·4-8(Ca, Co, Ni)O·2-4·As₂O₅·nH₂O. Fine lamellar to fibrous, extinction parallel, birefringence low, n variable 1.65-1.73. Mostly amorphous to x-rays.

Tuvite is a name applied to material constituting a further stage of the oxidation; it is yellow, brittle. The names are for the Khovakh deposits of the Tuva Autonomous Region, U.S.S.R.

Discussion.—As the abstractor states, it is impossible to determine whether these are minerals or mixtures. They should not have been named.

Parbigite

The mineral was found in drill core from a depth of 236 m. in the Parbig region, Tomsk oblast, in cavities in sandstone, associated with calcite and spheroidereite. It forms radial-fibrous aggregates, rarely pyramidal or prismatic crystals (0.5-1 mm). White, pale yellow, or colorless. Cleavage in one direction very perfect; under the microscope 4 cleavages were noted at angles: C₁-C₂=88°, C₁-C₃=72°, C₃-C₄=56°, C₄-C₅=49°. Luster silky to vitreous, H. about 3, G. 3.08. Optically biaxial, negative, ne 1.633, β 1.658, γ 1.670, 2V 70-74°, C:γ=18-23°. Easily fusible to a brown slag. Spectrographic analysis showed major Ca, Fe, P, Mg, minor Sr and Ba.

Discussion.—The difference in optical sign is insufficient basis for giving a new name. The mineral is presumably messelite.

Pallite

Chemical analyses and x-ray data show that the principal minerals present in the
aluminum phosphate zone are crandallite and pallite (=ferrian millisite), with minor augelite and rare wavelite and turquoise. Analyses of two samples estimated to contain 95% pallite + 5% crandallite gave, resp., \( \text{P}_2\text{O}_5 \) 26.28, 27.36; \( \text{Al}_2\text{O}_3 \) 25.74, 30.50; \( \text{MnO} \) 11.97, 9.86; \( \text{CaO} \) 6.94, 6.63; \( \text{MgO} \) 0.42, 0.53; Na\text{O} 1.95, 1.86; K\text{O} none, none; loss on ign. 15.98, 16.22; \( \text{SiO}_2 \) 5.36, 3.57; Ti\text{O} (insol.) 2.14, 1.63; Fe\text{O} (insol.) 1.14, 2.19; \( \text{MnO} \) 0.47, 0.00; F 0.46, 0.55; sum 98.85, 100.90. Uranium is present in amounts up to 140 ppm U in pallite and four times as much in crandallite.

The name is for the village of Pallo.

**Discussion.**—Unnecessary name for ferrian millisite.

**Hormites**

The name hormites is suggested by R. H. S. Robertson as a group name for the sepiolite-palygorskite group. The name is from the Greek for chain.

**Discussion.**—This is another example of the deplorable practice of cluttering the literature with unnecessary names (see *Am. Mineral.*, 41, 536 (1956)). I have urged repeatedly that such suggestions should be circulated privately for comment and should not be put into print until there is near unanimity on their desirability.

See note on page 244 of this issue.

**NEW DATA**

**Sterrettite, Kolbeckite**

X-ray fluorescence analysis of sterrettite from Fairfield, Utah, of “egggonite” from Altenberg, Belgium (?), and of kolbeckite from Schmeideberg, Saxony (type localities) showed that scandium is a major constituent. X-ray study (unit cells given) showed that the structure is of the metavariscite type and the formulas should be of the type \( \text{AX}_2\text{O}_7\cdot2\text{H}_2\text{O} \). Sterrettite, supposedly \( \text{Al}_6(\text{PO}_4(\text{OH})_6 \cdot \text{H}_2\text{O} \) (Dana’s system, 7th Ed., vol. 2, p. 965) is probably \( \text{ScPO}_4\cdot2\text{H}_2\text{O} \); the unit cell is nearly the same as for synthetic \( \text{ScPO}_4\cdot2\text{H}_2\text{O} \). The identity of egggonite with sterrettite is confirmed. Kolbeckite, supposedly a silicate-phosphate of Be, Ca, and Al (Dana’s system, 7th Ed., vol. 2, p. 1015–1016) may be \( (\text{Sc, Be, Ca})(\text{PO}_4, \text{SiO}_4)\cdot2\text{H}_2\text{O} \).

**Discussion.**—This doubles the number of minerals known to contain more than 1% \( \text{Sc}_2\text{O}_5 \).

**Irirginate**

Data available previously were summarized in *Am. Mineral.*, 43, 379 (1958). Additional data: Color canary-yellow, luster vitreous. Fracture uneven. Hardness 1–2, higher in aggregates. G. 3.84 (probably too low because of impurities). Indices of refraction, \( \alpha 1.733 \pm 0.003, \beta \sim 1.82, \gamma \sim 1.93 \). Extinction parallel. The mineral does not fluoresce. It is soluble in acids on heating. Analysis by M. M. Stukalova gave Mo\text{O}_3 38.62, U\text{O}_3 41.92, CaO 0.46, loss on ignition 9.70, insol. 9.04, sum 99.74%, corresponding to \( \text{MoO}_3 : \text{UO}_3 : \text{H}_2\text{O} =1.84 : 1:3.70 \) or \( \text{UO}_3 : 2\text{MoO}_3 : 4\text{H}_2\text{O} \). A potentiometric pH determination by N. I. Koma-
rova gave pH 4.4, so the formula is given as $\text{H}_2(\text{UO}_2)(\text{MoO}_4)_2 \cdot 3\text{H}_2\text{O}$. A D.T.A. curve shows a large and broad endothermic effect at 100-400°, a sharp exothermic effect at 480°.

X-ray powder patterns (more than 50 lines) were obtained by Yu. V. Kazitsyn in 1952 and A. I. Komkov in 1959. The former found strongest lines: 3.222 (10), 1.129 (8), 2.625 (6), 2.142 (6), 1.836 (6), 1.249 (6), 1.206 (6), 1.188 (6), 1.165 (6), 6.4 (5), 1.533 (5). The latter found 6.19 (10), 3.20 (9), 1.628 (9), 2.14 (8), 1.127 (8), 1.529 (7), 2.61 (6), 2.07 (6), 1.688 (6), 3.30 (5), 3.09 (5), 1.962 (5) 1.185 (5).

M. F.

Moluranite

Data available previously were summarized in Am. Mineral., 43, p. 380 (1958). Additional data: Isotropic, $n$ 1.97–1.98. G. about 4. Soluble in acids on heating. Light gray in reflected light, reflecting power about the same as that of pitchblende. Amorphous to X-rays. X-ray powder data on heated material correspond to those of U$_2$O$_3$. Analysis by M. M. Stukalova gave MoO$_3$ 38.50, UO$_2$ 10.30, UO$_3$ 32.35, SiO$_2$ 4.56, loss on ignition 14.03, sum 99.74%, corresponding to UO$_2$·3UO$_3$·7MoO$_3$·20H$_2$O. A D.T.A. curve shows a large and broad endothermic effect (40–400°) and small exothermic effects at 500°, 800°, and 980°.

M. F.

REDEFINITION OF MINERAL

Wiserite

The mineral wiserite, described in 1842 as a manganese oxide-carbonate and later discredited as pyrochroite, was shown by Epprecht in 1944 to give a distinctive x-ray pattern (see Am. Mineral., 32, 485 (1947)). Restudy shows that the previously published analyses were in error; the mineral is a hydrous borate, not an oxide or carbonate. The CO$_2$ reported was present as rhodochrosite.

Two samples were purified, and new analyses by A.C.V. gave: B$_2$O$_3$ 17.58, 16.32; MgO 2.79, 3.00 (spec. detn. by H. J. Rose); FeO tr., tr.; MnO 63.13, 65.23 (total Mn as MnO; a little MnO$_2$ was present); CaO 3.23, 0.75; H$_2$O+ 7.85, 8.00 (total H$_2$O); H$_2$O– 0.35, n.d.; Cl 3.02, 2.95; F none (<0.1), n.d.; CO$_2$ tr., tr.; Al$_2$O$_3$ (+ tr. Fe) 1.00, 0.45; insol. 1.20, 3.60; P$_2$O$_5$, SO$_3$ not present; total 100.15, 100.30 – (0–Cl) 0.68, 0.67 = 99.47, 99.63%; G. 3.42, n.d. These lead to the formula $4(\text{Mn, Mg, Ca})\text{O} \cdot 2\text{B}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$, with Cl replacing part of the H$_2$O (Better—$\text{Mn}_2\text{B}_2\text{O}_5$ (OH, Cl)); M.F.). Spectrographic analysis of a mixture of wiserite and an unknown mineral (Mineral X, see pg. 254) showed also traces of As, Bi, Cu, Ni, Pb, Sb, Sn, Sr, and Zn.

Rotation diagrams show wiserite to be tetragonal with $a = 14.27 \pm 0.01$, $c = 3.31 \pm 0.01$ kX, $Z = 4$. $c$ is parallel to the fibers, Cleavage is perfect across the fibers. Indexed x-ray powder photographs of 4 samples are given. The strongest lines (in kX) are 14.2 vs, 2.53 s, 6.40 ms. 3.36 ms, 2.87 ms, 2.35 ms.

Indices of refraction are somewhat variable: $a$ 1.700–1.717, $\gamma$ 1.753–1.76. Extinction parallel. Z is perpendicular, X parallel to the fiber direction, Uniaxial to slightly biaxial, negative. Weakly pleochroic with X bright—to dark orange-brown, Z colorless to bright orange-brown.

Wiserite occurs in fibers, intimately intergrown with pyrochroite, an unidentified mineral (see page 254), and sussexite (near the end member, optical and x-ray data given).

M. F.
