# The crystal structures of whewellite and weddellite: re-examination and comparison 

Vittorio Tazzoli and Chiara Domeneghetti

C.N.R. Centro di Studio per la Cristallografia Strutturale<br>c/o Istituto di Mineralogia dell 'Università, Pavia, Italy

#### Abstract

Whewellite, $\mathrm{CaC}_{2} \mathrm{O}_{4} \cdot \mathrm{H}_{2} \mathrm{O}$, and weddellite, $\mathrm{CaC}_{2} \mathrm{O}_{4} \cdot(2+x) \mathrm{H}_{2} \mathrm{O}$ where $x \leq 0.5$, occur in sediments, in plants, and in urinary stones. Their crystal structures have been refined to $R=0.033$ and $R=0.032$ respectively, using new sets of X-ray diffraction data, collected on a single-crystal diffractometer. Refined cell parameters are: $P 2_{1} / c, a=6.290(1), b=14.583(1), c=10.116(1) \mathrm{A}, \beta=$ 109.46(2) ${ }^{\circ}, Z=8$ for whewellite; $14 / m, a=12.371(3), c=7.357(2) \mathrm{A}, Z=8$ for weddellite.

During refinement of whewellite, three out of four H atoms could be located, and split positions, partially occupied, for the two independent water molecules were found. In weddellite refinement, it was possible to locate all the H atoms, and a split position for the "zeolitic" water was found; a maximum water content of $2.5 \mathrm{H}_{2} \mathrm{O}$ was confirmed. The comparison of the structures explains the relationships existing between some repeats of the two minerals and shows the differences between the Ca coordination polyhedra. A possible correlation between the structural features and the mechanism of formation of the two mineral species is suggested. The symmetry and planarity of the oxalate groups are discussed.

## Introduction

Whewellite and weddellite are hydrated oxalates of calcium, respectively $\mathrm{CaC}_{2} \mathrm{O}_{4} \cdot \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CaC}_{2} \mathrm{O}_{4} \cdot(2+x) \mathrm{H}_{2} \mathrm{O}$ (with $x \leq 0.5$ ), found naturally in plant tissues, in sediments as a mineral of organic origin, and in urinary stones. About 70 percent of human urinary stones contain whewellite and/or weddellite, either singly or mixed with other components, mostly phosphates, uric acids, or urates.

The frequency with which the two minerals are found in association in natural sources suggested a re-examination and a comparison of their crystal structure as the first stage of an investigation on their genetic relationships.

Previous structure analyses were carried out by Cocco (1961) and Cocco and Sabelli (1962) for whewellite (two-dimensional photographic data, $R=$ 0.14 ) and by Sterling (1965) for weddellite (three-dimensional photographic data, $R=0.13$ ).

## Experimental

Single crystals of whewellite and weddellite were obtained from urinary calculi. A Philips PW 1100 single-crystal diffractometer was used to collect the

X-ray diffraction data. Table 1 presents the experimental details. On the crystals of both species three standard reflections monitored at three-hour intervals showed less than 3.5 percent intensity variation during the data collection. X-ray data were processed with a locally modified version of a program specifically written for PW 1100 (Hornstra and Stubbe, 1972). Intensities were corrected for absorption following the method of North et al. (1968). Programs for structure determination, refinement and drawing of figures by Germain et al. (1971), Busing et al. (1962), and Johnson (1965) were employed. The scattering curves for neutral atoms given by the International Tables for $X$-ray Crystallography (1974) were used. High-precision methods using an $\omega$ scan of four intense reflections from each of several lattice rows provided accurate data for unit-cell parameter computations.

## Results of the structure refinements

## Whewellite

The orientation and the dimensions of the cell axes (Table 1) are consistent with one of the two alternative orientations proposed by Arnott et al. (1965)

Table 1. Crystal and diffraction data

(space group $P 2_{1} / c$ ). The values given for $c$ and $\beta$ by Cocco (1961) are not consistent with $P 2_{1} / c$ orientation assumed by this author, but seem to agree better with a $P 2_{1} / n$ orientation (Leavens, 1968).

The crystal structure, re-determined by means of the direct methods, is consistent with that published by Cocco (1961) and by Cocco and Sabelli (1962).

Isotropic temperature factors were used in the first least-squares cycles of the refinement; successively the atoms were treated anisotropically. A pseudo-cell with $b^{\prime}=b / 2$ (the intensities of the reflections with $k$ even are far greater than those of the reflections with $k$ odd) makes the atoms of the pairs $\mathrm{O}(1)-\mathrm{O}(3)$, $\mathrm{O}(2)-\mathrm{O}(4), \mathrm{Ca}(1)-\mathrm{Ca}(2), \mathrm{C}(3)-\mathrm{C}(4), \mathrm{O}(6)-\mathrm{O}(7)$, $\mathrm{O}(5)-\mathrm{O}(8)$, and $\mathrm{W}(1)-\mathrm{W}(2)$ pseudo-equivalent (see Fig. 1 and 2). In order to avoid correlation effects among the variables during calculations, the coordinates and thermal factors of the first or second atom of a pair were refined separately, as were the scale factor and the coefficient of secondary extinction (Zachariasen, 1963). From a difference Fourier map, three of the four hydrogen atoms were located and two maxima, double the height of that of the hydrogens, were interpreted as split positions of the two water molecules (respectively 0.73 and 0.39 A away
from them). The occupancy of these positions $\mathrm{W}(10)$ and $W(20)$ and, in turn, that of the main positions $\mathrm{W}(1)$ and $\mathrm{W}(2)$ were refined with other cycles of least squares, together with the coordinates and the anisotropic thermal factors of the non-hydrogen atoms. Fixed isotropic temperature factors were used for the atoms $\mathrm{H}(11), \mathrm{H}(21), \mathrm{H}(22), \mathrm{W}(10)$, and $\mathrm{W}(20)$. The final atomic parameters are shown in Tables 2 and 3; bond lengths and angles in Table 4. The observed and computed structure factors are compared in Table 5. ${ }^{1}$ The final value of the discrepancy index was $R=0.033$ for the 2864 observed reflections.

## Weddellite

The values of the cell parameters (Table 1) agree well with those of Sterling (1965). The atomic coordinates of this author, with the exclusion of those relative to oxygen of the "zeolitic" water, were used to start the refinement. During the first cycles, carried out using isotropic thermal factors, the examination of the difference Fourier map confirmed the presence of zeolitic water, with incomplete occupancy, in the channel running along the four-fold axis, with coordinates similar to those given by Sterling. In the last stages of refinement, difference Fourier maps allowed us to locate the hydrogen atoms of the two molecules of non-zeolitic water and to find a split position $\mathrm{W}(30)$ for the oxygen of the zeolitic water, the occupancy of which was refined alternately with that of the main position $W(3)$ (the distance between the two positions was 0.57 A ). Fixed isotropic temperature factors were used for the atoms $\mathrm{H}(5), \mathrm{H}(6)$, and W(30). The final atomic parameters are given in Tables 6 and 7, lengths and bond angles in Table 8. The observed and computed structure factors are compared in Table 9.' The final value of the discrepancy index was $R=0.032$ for the 889 observed reflections.

## Discussion and comparison of the structures

## Whewellite

In whewellite (Fig. 1) the coordination polyhedra of the pseudo-equivalent atoms $\mathrm{Ca}(1)$ and $\mathrm{Ca}(2)$ are distorted square antiprisms: in each of them seven of the oxygens belong to five oxalic groups and one to a water molecule. Each Ca polyhedron shares three edges with three adjacent Ca polyhedra. In this way

polyhedral layers are formed parallel to (100), the good cleavage plane. Within the layers, Ca atoms occur at the vertices of hexagons which have at their center one of the two independent oxalic groups. These oxalic groups lie in the (100) plane with the $\mathrm{C}(1)-\mathrm{C}(2)$ bonds nearly parallel to the $b$ axis. The layers are connected to one another through the second series of oxalic groups and the water molecules (Fig. 2): oxalic groups alternate with the water molecules and form ribbons lying in the (010) plane and running along $c$. Bonding between the pseudo-equivalent water molecules $W(1)$ and $W(2)$ and the pseudo-equivalent oxygens $\mathrm{O}(8)$ and $\mathrm{O}(5)$ is through the pseudo-equivalent hydrogen atoms $\mathrm{H}(11)$ and $\mathrm{H}(21)$. The bond between the two water molecules takes place through hydrogen $\mathrm{H}(22)$. The hydrogen atom $\mathrm{H}(12)$, which probably does not take part in hydrogen bonds and which, in any case, cannot respect the pseudo-symmetry with $\mathrm{H}(22)$ for steric reasons, was not identified.

## Weddellite

In weddellite the calcium coordination polyhedron is a distorted square antiprism but, of the eight oxy-

gens, six belong to four oxalic groups and two to water molecules: with respect to whewellite, calcium is coordinated to one less oxalic group and one more water molecule. If we assume that in solution the formation of calcium oxalates and their precipitation take place by substitution, in the $\mathrm{Ca}^{2+}$ hydration sphere, of the water molecules with oxalate ions, weddellite should be the first stage of this process.

Each polyhedron of calcium in weddellite makes a link to two adjacent polyhedra (Fig. 3), changing the layers found in whewellite to chains running along $c$ (axis 4). The link between these chains is made by

| $O(2)-C-C$ | $116.15(12)$ | $H(2)-W(2)-H(2)$ | $107.11(29)$ |
| $O(1)-C-C$ | $117.17(11)$ |  |  |

means of ( $\cdots$ oxalate-water-oxalate $\cdots$ ) ribbons lying in planes parallel to (100). In these ribbons the water molecules $\mathrm{W}(1)$ and $\mathrm{W}(2)$ and the oxygens $\mathrm{O}(2)$ are bonded through hydrogens $\mathrm{H}(5)$ and $\mathrm{H}(6)$.

The repetition around the four-fold axis of the Ca chains and the oxalate-water ribbons generate a channel (Fig. 4) in which zeolitic water occurs in two alternative and very close positions, W(3) and W(30). The distance between two W(3) water molecules related by a symmetry center corresponds to that of a strong hydrogen bond; the closest contacts of water W(30) occur with four non-zeolitic W(1) waters. The sum of the occupancies of the two alternative positions W(3) and W(30) turns out to be $O c c=0.58+$ $0.17=0.75$, which, taking multiplicity into account, brings the contribution of zeolitic water to 0.37 ; thus the formula of the weddellite examined is $\mathrm{CaC}_{2} \mathrm{O}_{4} \cdot 2.37 \mathrm{H}_{2} \mathrm{O}$.

Sterling (1965) observed that the multiplicity of the position of the zeolitic water limits the maximum water content of weddellite to $2.5 \mathrm{H}_{2} \mathrm{O}$; however, Gérard et al. (1968) later postulated the existence of weddellite with three molecules of water, on the basis of thermal analyses of samples kept in water-vaporcontrolled atmosphere. In order to check this hypothesis, a systematic research of possible cavities existing in the structure was carried out; two "holes" (with coordinates $0,0.50,0.25$ and $0,0,0$ ) were identified, but they appear too small to hold water molecules, which in this case would have too short contacts (less than 2.35 A ) with other water molecules. Therefore a

greater degree of hydration implies another crystalline phase, which could be that of the trihydrate hypothesized by some authors (Walter-Levy and Laniepiece, 1964; Gérard et al., 1968; Doremus et al., 1976).

## Planarity and symmetry of the oxalic groups

The deviations of the atoms from the least-squares plane (Table 10) and the difference among the bond
lengths and angles in each group were submitted to a significance test (Stout and Jensen, 1968, p. 419-421). It was found that:
(a) in whewellite the oxalic group $\mathrm{C}(1), \mathrm{C}(2) \ldots$ appears to be planar, with a symmetry not higher than 2 mm , and the oxalic group $\mathrm{C}(3), \mathrm{C}(4) \ldots$ appears to be significantly non-planar, with a symmetry 1 ;
(b) in weddellite the oxalic group appears to be

Table 10. Deviations from planarity in oxalic groups

[^2]Table 11. Significant repeats in whewellite and weddellite
Sequence
planar, with a symmetry not higher than 2 mm and not lower than $m$ (crystallographic symmetry); mmm symmetry as proposed by Sterling (1965) must be excluded, consistent with the remarkable difference between the environments and bonds of $O(1)$ and $O(2)$.

## Conclusions

The comparison between the crystal structures of weddellite and whewellite reveals marked similarities, which are in agreement with the frequent association of the two minerals and with the easy transformation of the former into the latter.

A simple scheme of linear dimensions (Table 11) shows and explains, with the help of the figures, the relationships existing between some significant repeats of the two compounds (in particular the ratio $c_{\text {wedd }} / b_{\text {whew }}=1 / 2$ ) and displays the distortion of the structure resulting from the dehydration of weddellite to whewellite, which appears clearly by observing, along the repeats $[201]_{\text {whew }}$ and $[100]_{\text {wedd }}$, the change of the hydrogen bond system.

All the structural details given here could be of some interest for the study of the growth morphology of whewellite and weddellite and the possible epitaxial relations between the two minerals hypothesized by Lonsdale (1968) in urinary stones; in addition the structural relations will aid in the understanding of the kinetics of formation and transformation of these
compounds on which investigations are in progress in this laboratory.
