**ABSTRACT**

The pressure-volume-temperature (P-V-T) equation of state (EoS) of synthetic uvarovite has been measured at high temperatures up to 900 K and high pressures up to 16.20 GPa, by using in situ angle-dispersive X-ray diffraction and diamond-anvil cell. Analysis of room-temperature P-V data to a third-order Birch-Murnaghan EoS yielded: \( V_0 = 1736.9 \pm 0.5 \, \text{Å}^3 \), \( K_0 = 162 \pm 2 \, \text{GPa} \), and \( K'_0 = 4.5 \pm 0.3 \). With \( K'_0 \) fixed to 4.0, we obtained: \( V_0 = 1736.5 \pm 0.3 \, \text{Å}^3 \) and \( K_0 = 164 \pm 1 \, \text{GPa} \). Fitting of our P-V-T data by means of the high-temperature third-order Birch-Murnaghan equations of state, given the thermoelastic parameters: \( V_0 = 1736.8 \pm 0.8 \, \text{Å}^3 \), \( K_0 = 162 \pm 3 \, \text{GPa} \), \( K'_0 = 4.3 \pm 0.4 \), \( (\partial K/\partial T)_0 = -0.021 \pm 0.004 \, \text{GPa/K} \), and \( \alpha_0 = (2.72 \pm 0.14) \times 10^{-5} \, \text{K}^{-1} \). We compared our elastic parameters to the results from the previous studies for uvarovite. From the comparison of these fittings, we propose to constrain the bulk modulus and its pressure derivative to \( K_0 = 162 \, \text{GPa} \) and \( K'_0 = 4.0 \) for uvarovite. Present results were also compared with previous studies for other ugrandite garnets, grossular and andradite, which indicated that the compression mechanism of uvarovite might be similar with grossular and andradite. Furthermore, a systematic relationship, \( K_0 \) (GPa) = 398.1(7)–0.136(8) \( V_0 \) (Å³) with a correlation coefficient \( R^2 \) of 0.9999, has been established based on these isostructural analogs. Combining these results with previous studies for pyrralspite garnets—pyrope, almandine, and spessartine—the compositional dependence of the thermoelastic parameters (bulk modulus, thermal expansion, and the temperature derivative of the bulk modulus) were discussed.

**INTRODUCTION**

Silicate garnets are considered important rock-forming minerals of the Earth’s interior existing in the upper mantle and transition zone, comprising up to 40% by volume of the pyrolite composition and up to 70% of eclogitic composition (Akaogi and Akimoto 1977; Anderson and Bass 1984; Irifune and Ringwood 1987; Ita and Stixrude 1992; Dymshits et al. 2014). They occur as stable phases in a wide range of pressures, temperatures, and chemical environments, and play a fundamental role in high-pressure and high-temperature petrogenetic processes (Deer et al. 1992; Pavese et al. 2001). Garnets are also important components of subducted oceanic crust, and it is suggested that garnet-rich subducted crust can be gravitationally trapped in the lowermost part of transition zone (Irifune and Ringwood 1993; Karato et al. 1995). In addition, former experiments at high pressure and high temperature on garnets showed that post-garnet transitions occur at pressure and temperature conditions relatively close to the ones of the 660 km depth discontinuity (Irifune et al. 1996; Akaogi et al. 1998; Gréaux et al. 2011a, 2011b). Therefore, understanding the thermoelastic properties of garnets is essential to infer appropriate compositional models and regional seismic profiles of the Earth’s interior (Duffy and Anderson 1989; Weidner and Wang 2000).

The minerals of the garnet group are divided into two series, pyrralspite and ugrandite. Uvarovite is a chromium-bearing ugrandite garnet group species with the formula Ca₃Cr₂Si₃O₁₂ and is thus distinguished from both grossularite (Ca₃Al₂Si₃O₁₂) and andradite (Ca₃Fe₂Si₃O₁₂). Uvarovite is one of the rarest of the garnet group minerals, but nonetheless prevalent in many terrains and geologic settings (Green and Falloon 1998; O’Neill and Palme 1998; Chopelas 2005; Klemme et al. 2005), and its thermoelastic behavior at high pressure and high temperature will shed light on other ugrandite garnets, as well as pyrralspite garnets. It can form a complete solid-solution series with grossular and andradite in the Earth’s interior (Huckenholz and Knittel 1975). Uvarovite has generally been found associated with serpentinite, chrome, metamorphic limestones, and skarn ore-bodies; it has formed from contact metamorphic processes or hydrothermal processes (Challis et al. 1995; Graham et al. 1996; Proenza et
