

Supplementary material for:

**A vibrational spectroscopic study of kernite to 25 GPa: implications for the high-pressure
stability of borate polyhedra**

Marcus Silva, Earl F. O'Bannon III, and Quentin Williams

Department of Earth & Planetary Sciences, University of California Santa Cruz

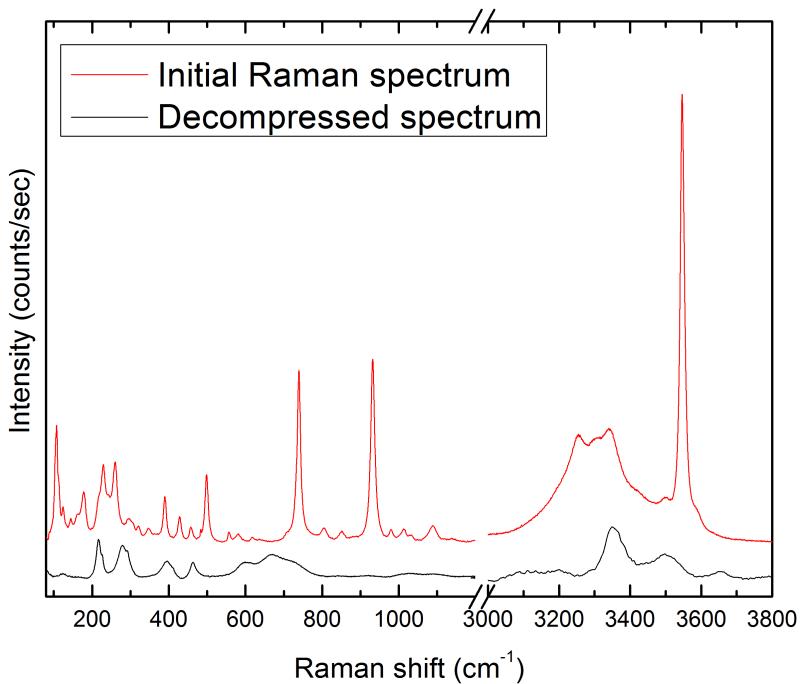

Figure S1. A comparison between the ambient starting Raman spectrum and the Raman spectrum decompressed from ~ 25 GPa of kernite. While the spectra as a whole are entirely distinct from one another, the difference in the low frequency region (< 200 cm^{-1}) is particularly dramatic; only two low intensity broad modes are present in the quenched material.

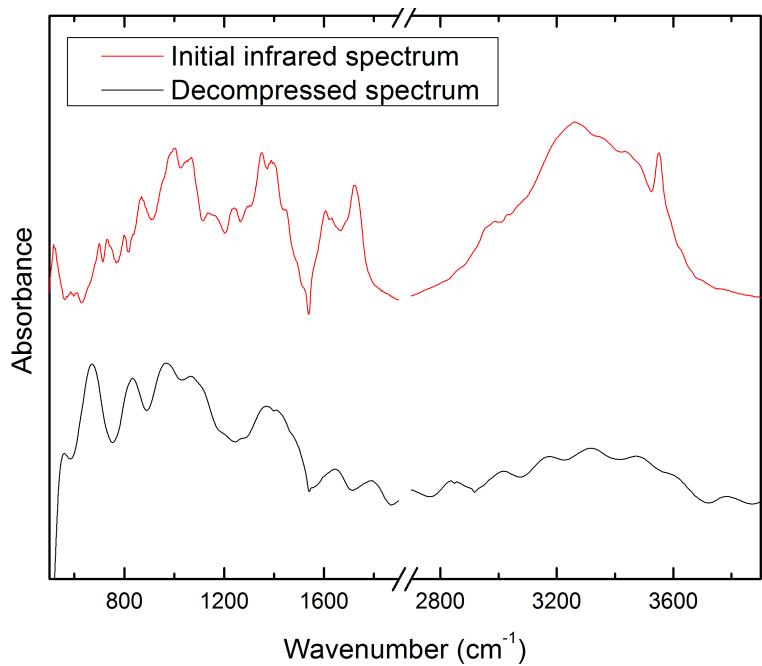

Figure S2. A comparison of the ambient starting infrared spectrum and the decompressed infrared spectrum from ~22 GPa of kernite.

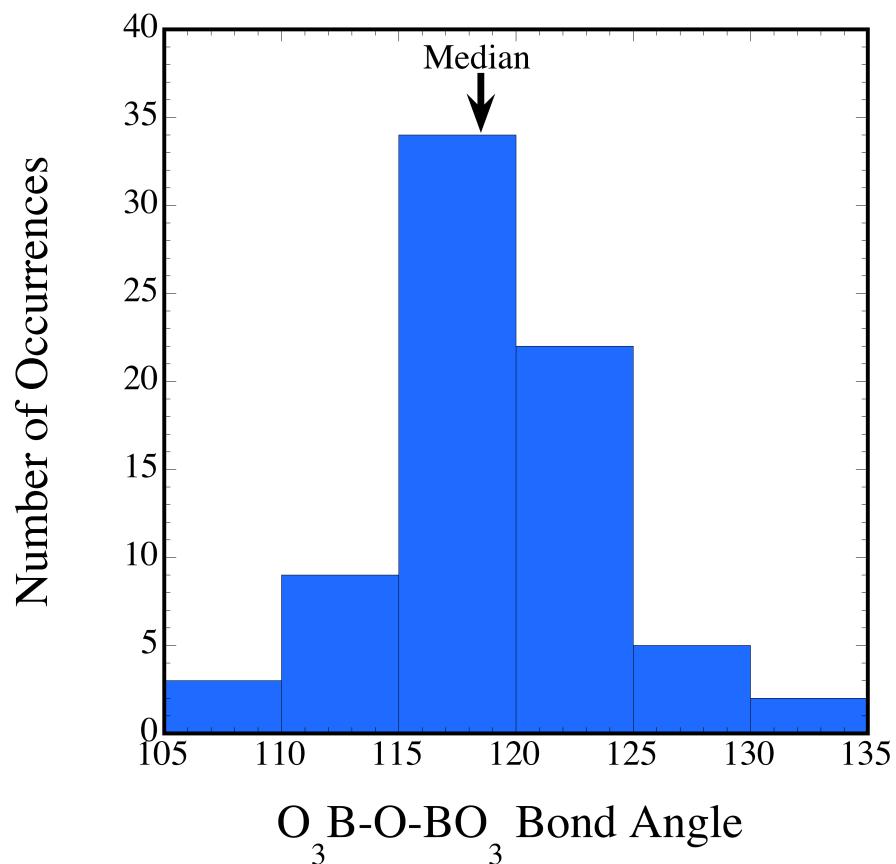

Figure S3. Bond angles between adjoining borate tetrahedra in boron-bearing phases at ambient pressures, using the results of Table S1.
