### ABSTRACT

<sup>26</sup>Mg tracer diffusion coefficients were determined in single crystals of pure synthetic forsterite (Mg<sub>2</sub>SiO<sub>4</sub>). Isotopically enriched powder sources both acted as the <sup>26</sup>Mg source and buffered the activities of silica ( $a_{\text{SiO}_2}$ ) at forsterite + protoenstatite (Mg<sub>2</sub>Si<sub>2</sub>O<sub>6</sub>) (high  $a_{\text{SiO}_2}$ ) and forsterite + periclase (MgO) (low  $a_{\text{SiO}_2}$ ). Experiments were conducted at atmospheric pressure between 1250 and 1600 °C, and at oxygen fugacities ( $f_{\text{O}_2}$ s) between 10<sup>-12</sup> bars (CO-CO<sub>2</sub> mix) and 10<sup>-0.7</sup> bars (air). The resulting diffusion profiles were measured along the three principal crystallographic axes ( $a$ ,  $b$ , and  $c$ ;  $\parallel$ [100],  $\parallel$ [010],  $\parallel$ [001]) using laser ablation–inductively coupled plasma–mass spectrometry (LA-ICP-MS), with a quadrupole mass spectrometer. These measurements were corroborated by ion microprobe using the sensitive high resolution ion microprobe-reverse geometry (SHRIMP-RG) instrument.

Mg tracer diffusion is anisotropic, with  $D_{[001]} > D_{[010]} > D_{[100]}$ , the difference in diffusion coefficients varying by about one order of magnitude at a given temperature with crystallographic orientation. Diffusion is faster in protoenstatite-buffered than periclase-buffered conditions, again with around one order of magnitude difference in diffusivity between buffering conditions. There is no apparent effect of  $f_{\text{O}_2}$  on diffusion. A global fit to all data, including data from Chakraborty et al. (1994) and Morioka (1981) yields the relationship:

$$\log_{10} D = \log_{10} D_0 (m^2 s^{-1}) + 0.61 (\pm 0.03) \log_{10} a_{\text{SiO}_2} + \frac{-359 (\pm 10) \text{kJ/mol}}{2.303RT}$$

where  $\log_{10} D_0$  is  $-3.15 (\pm 0.08)$ ,  $-3.61 (\pm 0.02)$ , and  $-4.01 (\pm 0.05) \text{ m}^2 \text{ s}^{-1}$  for the [001], [010], and [100] directions, respectively (1 s.d.). The LA-ICP-MS technique reproduces diffusion coefficients determined by SHRIMP-RG, albeit with slightly different absolute values of isotope ratios. This shows that LA-ICP-MS, which is both accessible and rapid, is a robust analytical method for such tracer diffusion studies.
