21                                                      **Abstract**

22    Crocobelonite, $CaFe^{3+}_2(PO_4)_2O$, is a new natural oxyphosphate discovered in the pyrometamorphic

23    complexes of the Hatrurim Formation in Israel and Jordan. Crocobelonite-bearing assemblages

24    contain a series of anhydrous Fe-Ni phosphates, hematite, diopside, anorthite, and phosphides –

25    barringerite $Fe_2P$, transjordanite $Ni_2P$, murashkoite FeP, halamishite $Ni_5P_4$, and negevite $NiP_2$.

26    Crocobelonite forms submillimeter-sized aggregates of prismatic to acicular crystals of saffron-red

27    to pinkish-red colour. There are two polymorphic modifications of the mineral whose structures are

28    interrelated by the unit-cell twinning. Crocobelonite-$2O$ is orthorhombic, $Pnma$, $a$ 14.2757(1), $b$

29    6.3832(1), $c$ 7.3169(1) Å, $V$ 666.76(1) Å$^3$, $Z = 4$. This polymorphic modification is isotypic with

30    synthetic oxyphosphates $AV^{3+}_2(PO_4)_2O$ where $A$ = Ca, Sr, Cd. The crystal structure has been refined

31    to $R_B = 0.71\%$ based on the powder XRD data, using the Rietveld method and the input structural

32    model obtained from the single-crystal study. Chemical composition (electron microprobe, wt.%) is:

33    CaO 16.03, MgO 0.56, $Fe_2O_3$ 43.37, $Al_2O_3$ 0.33, $SiO_2$ 0.32, $P_2O_5$ 39.45, Total 100.06. The empirical

34    formula based on O = 9 $apfu$ is $Ca_{1.02}(Fe^{3+}_{1.94}Mg_{0.05}Al_{0.02})_{2.01}(P_{1.98}Si_{0.02})_{2.00}O_{9.00}$ with $D_{calc.}$ = 3.555 g

35    cm$^{-3}$. The strongest lines of powder XRD pattern $[d(Å)(I)(hkl)]$ are: 6.54(16)(200), 5.12(26)(201),

36    3.549(100)(102), 3.200(50)(401), 2.912(19)(220), 2.869(40)(411), 2.662(21)(501). Crocobelonite-

37    $1M$ is monoclinic, $P2_1/m$, $a$ 7.2447(2), $b$ 6.3832(1), $c$ 7.3993(2) Å, $\beta$ 106.401(2)°, $V$ 328.252(14) Å$^3$,

38    $Z = 2$. This polymorphic modification does not have direct structural analogues. Its crystal structure

39    has been solved and refined based on the single-crystal data to $R_1 = 1.81\%$. Chemical composition

40    is: CaO 15.56, MgO 0.16, NiO 0.78, $Fe_2O_3$ 41.28, $Al_2O_3$ 0.45, $V_2O_3$ 0.42, $Cr_2O_3$ 0.23, $TiO_2$ 0.79,

41    $P_2O_5$ 39.94, Total 99.61, corresponding to the empirical formula (O = 9 $apfu$)

42    $Ca_{0.99}(Fe^{3+}_{1.85}Ni_{0.04}Ti_{0.04}Al_{0.03}V^{3+}_{0.02}Cr_{0.01}Mg_{0.01})_{2.00}P_{2.01}O_{9.00}$ with $D_{calc.}$ = 3.604 g cm$^{-3}$. The

43    strongest lines of powder XRD pattern $[d(Å)(I)(hkl)]$ are: 6.98(17)(100), 4.40(22)(101),

44    3.547(100)(–201), 3.485(21)(200), 3.195(50)(020), 2.855(38)(102), 2.389(33)(–122). Crocobelonite

45      represents a specific novel type of phosphate mineralization formed by oxidation of phosphide

46      minerals at temperatures higher than 1000 °C and near-atmospheric pressure (pyrolytic oxidation).

51

**Introduction**

52

53   Since the discovery of combusted sedimentary beds in the Judean Desert (Picard 1931) and the

54   recognition of similar rocks elsewhere in Israel, Palestinian Authority and Jordan (Bentor et al.1963;

55   Gross 1977; Khoury and Nassir 1982a,b; Burg et al. 1992), pyrometamorphic complex known as the

56   Hatrurim Formation or the Mottled Zone (Fig. 1) attracts substantial mineralogical interest. A

57   combination of high-temperature combustion processes, intense hydrothermal activity and

58   weathering in a desert climate have lead to the emergence of dozens of exotic mineral species (e.g.,

59   Sokol et al. 2014, 2019; Britvin et al. 2015, 2022a; Khoury 2020). As an example, the anomalous

60   chromium mineralization is represented by a suite of $Cr^{3+}$ species, such as bentorite

61   $Ca_6Cr_2(SO_4)_3(OH)_{12} \cdot 26H_2O$ (Gross 1980) and ellinaite $CaCr_2O_4$ (Sharygin et al. 2021; Galuskina et

62   al. 2021a), along with chromates – chromatite $CaCrO_4$ (Eckhardt and Heimbach 1963), hashemite

63   $BaCrO_4$ (Hauff et al. 1983), and siwaqaite, $Ca_6Al_2(CrO_4)_3(OH)_{12} \cdot 26H_2O$ (Juroszek et al. 2020).

64   Selenium is being incorporated into selenides ($Se^{2-}$) (Sokol et al. 2014) and selenates ($SeO_4^{2-}$)

65   (Juroszek et al. 2020). Calcium, the classic lithophile element, forms sulfides – oldhamite CaS and

66   dzierżanowskite, $CaCu_2S_2$ (Galuskina et al. 2017). Other mineralogical highlights include oxides,

67   such as grossite, $CaAl_4O_7$, discovered simultaneously in the Hatrurim Formation and within

68   calcium-aluminium inclusions (CAI) of carbonaceous chondrites (Weber and Bischoff 1994);

69   perovskite-supergroup minerals: vapnikite – the double perovskite $CaCaUO_6$ (Galuskin et al. 2014),

70   shulamitite $Ca_3TiFe^{3+}AlO_8$ (Sharygin et al. 2013), cubic oxygen-deficient perovskite

71   $Ca(Ti,Si,Cr)O_{3-\delta}$ (Britvin et al. 2022c), and aluminate garnet priscillagrewite-(Y), $(Ca_2Y)Zr_2(AlO_4)_3$

72   (Galuskina et al. 2021b).

73        Pyrometamorphic rocks of the Hatrurim Formation are enriched in phosphorus (e.g., Al-

74   Ajarmeh and Khoury 2018), which can appear in the form of phosphides – rare minerals containing

75   this element in a negative oxidation state (Britvin et al. 2015). To date, twelve phosphide minerals,

4

76 including nine new species, were recognized in Israel and Jordan. In the course of an ongoing

77 research of phosphide assemblages, the authors of the present paper have discovered a suite of

78 natural phosphates genetically related to phosphides (Britvin et al. 2021a). We herein introduce the

79 reader with the most abundant representative of this mineralization – a new oxyphosphate

80 $CaFe^{3+}_2(PO_4)_2O$. The mineral was named crocobelonite, from Greek κρόκος (saffron) and βελόνα

81 (needle), for the orange-red colour and prismatic to acicular habit of its crystals. Both the mineral

82 and the name have been approved by the Commission on New Minerals, Nomenclature and

83 Classification (CNMNC) of the International Mineralogical Association (IMA 2020-005). Since the

84 IMA approval of crocobelonite, it was found that the mineral could form two polymorphic

85 modifications. The originally described polymorph (IMA 2020-005) crystallizes in the orthorhombic

86 symmetry. The subsequently discovered monoclinic dimorph was proposed by the authors and

87 submitted for voting to CNMNC as a distinct species (IMA 2021-038). However, based on the

88 topological similarity of the crystal structures of both polymorphs (Nickel and Grice 1998),

89 CNMNC has decided to leave the same root name (i.e., crocobelonite) for both polymorphic

90 modifications. According to the CNMNC decision based on voting results, the orthorhombic

91 dimorph (IMA 2021-038) was named crocobelonite-2*O*, whereas its monoclinic counterpart has got

92 the name crocobelonite-1*M*. According to the Strunz classification (Strunz and Nickel 2001),

93 crocobelonite belongs to the group 8.AC - anhydrous phosphates with additional anions, and with

94 medium-sized and large cations. Within the Dana's system of mineralogy (Gaines et al. 1997),

95 crocobelonite is related to the group 38.05 (anhydrous phosphates, etc with miscellaneous

96 formulae). The holotype specimens of crocobelonite-2*O* (registration number 5559/1) and

97 crocobelonite-1*M* (5683/1) are deposited in the collections of the Fersman Mineralogical Museum of

98 the Russian Academy of Sciences, Moscow, Russia.

99

## Geological setting and occurrence

100

101    The outcrops of pyrometamorphic rocks belonging to the Hatrurim Formation are sporadically

102    exposed over the area of 150×200 km$^2$ surrounding the Dead Sea basin, and to the north, along the

103    Jordan River valley to the Jordan-Syria-Israel border junction (Fig. 1). From a tectonic point of

104    view, this area belongs to the Dead Sea Transform fault system (Garfunkel and Ben-Avraham 1996;

105    Ben-Avraham et al. 2008). The reviews in geology and stratigraphy of this region can be found

106    elsewhere (Burg et al. 1992; Fleurance et al. 2013; Abzalov et al. 2015). The sediments subjected to

107    pyrometamorphic processes were represented by chalky-marly sequences of late Cretaceous to

108    Eocene age. A brief stratigraphic overview and relationships between the sequences in Israel and

109    Jordan can be found in Britvin et al. (2022b). The geological dating of combusted rocks gave

110    controversial results, from 16 Ma to 250 Ka (Gur et al. 1995; Kolodny et al., 2014); the former value

111    is approximately coincident with the onset of tectonic activity at the Dead Sea Transform Fault. The

112    wide range of age dating may evidence for multiple pyrometamorphic events occurred in the region.

113    The temperatures during combustion processes could attain 1450 °C (Sharygin et al. 2016), that lead

114    to the calcination and even fusion of sedimentary beds, with formation of varicoloured marbles,

115    hornfels and the so-called paralava – fused counterparts of igneous rocks (Vapnik et al. 2007). There

116    is an overall consensus that pyrometamorphic processes were driven by the combustion of organic

117    matter, but the definition and the origin of this organic substance remains obscure, varying from

118    bitumen (e.g., Kolodny and Gross 1974) to oil gas (methane) (Novikov et al. 2013). The possible

119    initial event that could trigger combustion processes over such a vast area is also obscure (Britvin et

120    al. 2021b, 2022c).

121        The known enrichment of pyrometamorphic rocks of the Mottled Zone in phosphorus can be

122    relied upon the entrapment of underlying phosphorite beds, which are widespread in this area

123    (Nathan et al. 1979; Abzalov et al. 2015; Khoury 2019). Phosphorite xenoliths of black colour,

6

124  partially assimilated by varicoloured hornfels, can be found in phosphorite and stone quarries, which

125  tip the hills belonging to the Hatrurim Formation in the Daba-Siwaqa complex, West Jordan (Fig.

126  2ab). A deeper metamorphic transformation of entrapped phosphorites resulted in the emergence of

127  fine-grained fluorapatite (e.g., Al-Ajarmeh and Khoury 2018). The latter has an intense blue-green

128  to emerald-green colour due to the trace amounts of $Cr^{3+}$ in its composition (Fig 2c). Fluorapatite is

129  considered a likely source of phosphorus, which was required for phosphides formation (Britvin et

130  al. 2015, 2021a).

131        The type locality for crocobelonite-2*O* is a small abandoned quarry formerly operated for

132  phosphorites, located at the Daba-Siwaqa complex in the Jizah District, Amman Governorate,

133  Jordan (31° 21' 52" N, 36° 10' 55" E) (Fig. 1 and 2a). In this quarry, phosphide-phosphate

134  assemblages containing crocobelonite are comprised by diopside paralava and appear as nests and

135  schlieren up to 30 cm in size situated in brown to red-colored hornfels (Fig. 2a). Macroscopically,

136  the paralava nests have pale-brown colour, whereas the areas enriched in phosphates are colored in

137  greenish-brown hues (Fig. 3a). The paralava consists of random to radial aggregates of colorless

138  long-prismatic diopside crystals up to 0.2×3 mm in size, cemented by late hydrothermal calcite and

139  hydrous calcium silicates (Fig. 3b,c). Diopside composition is close to pure $CaMgSi_2O_6$, with Fe and

140  Al impurities of less than 0.1 wt.%. Phosphates, including crocobelonite, form bubble-like

141  segregations of brown color up to 1 cm size, disseminated in paralava. In thin sections, these

142  bubbles exhibit very inhomogeneous interior (Fig 3d). They are filled with aggregates of round

143  grains 0.05-0.5 mm in size, whose internal texture (Fig. 3e) resembles that of radial and

144  cryptocrystalline chondrules of chondritic meteorites (e.g., Kurat 1969; Grossman et al. 2000). The

145  droplets are composed of calcium silico-phosphate glass and unidentified anhydrous calcium silico-

146  phosphates; the mesostasis between the droplets has the similar composition. The peripheral rims of

147  centimeter-sized bubbles are composed of microcrystalline hematite, phosphides – murashkoite FeP

7

148    (Britvin et al. 2019b), zuktamrurite $FeP_2$ (Britvin et al. 2019a), barringerite $Fe_2P$ and transjordanite

149    $Ni_2P$ (Britvin et al. 2020a), halamishite $Ni_5P_4$, negevite $NiP_2$ (Britvin et al. 2020b,c) and a variety of

150    anhydrous phosphates (Fig. 3f), of which crocobelonite is the most abundant.

151            Crocobelonite-1*M* was primarily recognized in phosphide-phosphate assemblages

152    encountered in detrital blocks of diopside paralava collected at the Halamish wadi, the Hatrurim

153    Basin, Negev desert, Israel. The detailed description of this locality was recently reported by Britvin

154    et al. (2022b). The specimens from the Hatrurim Basin do not contain bubble-like phosphate-

155    phosphide aggregates, but in other terms are very similar to the samples from the Jordan locality.

156    Subsequent investigations have revealed that both polymorphic modifications of crocobelonite occur

157    together in the samples collected in Jordan and Israel.

158

159                                    **Analytical Methods**

160    ***Electron microprobe analysis (EMPA) and electron backscatter diffraction (EBSD)***

161    Determinations of the chemical composition were carried out on polished and carbon-coated

162    sections using a Hitachi S-3400N scanning electron microscope equipped with an INCA WAVE 500

163    WDX spectrometer (20 kV, 10 nA), using the following standards (*K*α series lines): diopside (Ca,

164    Si), rutile (Ti), chromite (Cr), V metal (V), hematite (Fe), trevorite (Ni), gehlenite (Al), and

165    chlorapatite (P). EBSD phase determination and mapping was performed on the same polished

166    sections, after reactive ion etching (RIE) with $Ar^+$ by means of an Oxford Instruments IonFab-300

167    instrument (500 V, 2.4 mA $cm^{-2}$ flow current). EBSD patterns were obtained using an Oxford

168    Instruments Nordlys-HKL EBSD detector (20 kV, 1.5 nA, focused beam mode, 70° tilted stage)

169    attached to a Hitachi S-3400N scanning electron microscope. Phase identification was carried out

170    using the atomic coordinates obtained from X-ray structural refinements.

171

8

172   *Powder X-ray diffraction (PXRD) and Rietveld refinement*

173   PXRD patterns were obtained by means of a Rigaku RAXIS Rapid II diffractometer. The instrument

174   was equipped with a rotating anode (Co$K\alpha$, 40 kV, 15 mA), microfocus mirror monochromator and

175   semi-cylindrical imaging plate detector ($r$ = 127.4 mm). The images were acquired in a Debye-

176   Scherrer geometry. A plate-to-profile data conversion was carried out using osc2xrd software

177   (Britvin et al. 2017). The unit-cell parameters refinement and calculation of theoretical patterns was

178   performed with Stoe WinXPOW software (Stoe and Cie GmbH). Rietveld refinement of PXRD

179   profile of crocobelonite-2$O$ was carried out with Bruker TOPAS v.5.0 software (Bruker AXS).

180   *Single-crystal X-ray diffraction (SCXRD) and crystal structures*

181   SCXRD studies were carried out for both crocobelonite polymorphs. Data collection for

182   crocobelonite-2$O$ was performed using a Bruker Kappa APEX DUO CCD diffractometer

183   (microfocus tube, Mo$K\alpha$ radiation). Data collection for crocobelonite-1$M$ was carried out with a

184   Rigaku Oxford Diffraction XtaLAB Synergy-S diffractometer equipped with a microfocus X-ray

185   tube (Mo$K\alpha$) and HyPix-6000 hybrid photon counting detector. Data processing and integration

186   routines were completed using Rigaku Oxford Diffraction CrysAlisPro program suite (Rigaku

187   Oxford Diffraction 2018). The crystal structures were solved and refined with the *SHELX*-2018

188   package (Sheldrick 2015) via Olex2 graphical user interface (Dolomanov et al. 2009). The details of

189   data collection and structure refinement for both crocobelonite polymorphs can be retrieved from

190   crystallographic information files (CIF) in Supplementary Data. The SCXRD CIF file consists of

191   two datablocks. The first block contains the best SCXRD refinement results obtained for

192   crocobelonite-2$O$; these data were used as an input model for the Rietveld refinement of

193   crocobelonite-2$O$. The third datablock contains SCXRD refinement results for crocobelonite-1$M$.

194   Rietveld refinement results for crocobelonite-2$O$ are given in the separate CIF file.

195

196     *Raman spectroscopy*

197     Raman spectra for both polymorphic modifications of crocobelonite were obtained from the X-ray

198     checked crystals, using a Horiba Jobin-Yvon LabRam HR800 spectrometer equipped with an Ar-ion

199     laser (5 mW, $\lambda = 514$ nm) and an Olympus BX41 microscope, using a 50× confocal objective.

200

201     **Appearance and physical properties**

202     Crocobelonite occurs as irregular dense segregations up to 0.5 mm, intergrown with diopside,

203     anorthite, hematite, phosphate-silicate glass and other phosphate minerals (Fig. 3f). Phosphides, in

204     general murashkoite FeP, zuktamrurite $FeP_2$, and the minerals belonging to the join barringerite

205     $Fe_2P$ - transjordanite $Ni_2P$, occur in the same areas. In the rarely found microcavities, crocobelonite

206     forms prismatic to acicular crystals reaching 30×150 μm in size (Fig. 4). The mineral has a saffron-

207     red (crocoite-like) colour in dense aggregates, whereas single crystals exhibit distinct dichroism

208     from pink-red to deep-red. Crocobelonite gives an orange strike and has a vitreous to greasy colour.

209     It is brittle and shows a perfect cleavage in two directions (crocobelonite-2*O*) and in one direction

210     (crocobelonite-1*M*), parallel to crystals elongation. Mohs hardness 4. The density, calculated based

211     on the empirical formula and unit-cell parameters, is 3.555 g cm$^{-3}$ (2*O* polymorph) and 3.604 g cm$^{-3}$

212     (1*M* polymorph). Crocobelonite-2*O* and crocobelonite-1*M* are visually indistinguishable from each

213     other, neither in macrosamples nor in thin sections. Moreover, they may occur in the same μm-sized

214     assemblages and even to form mutual intergrowths (Fig. 5). The most reliable method to distinguish

215     the polymorphs is the X-ray study. In polished thin sections, the 2*O* and 1*M* modifications can be

216     distinguished using electron backscatter diffraction (EBSD) (Fig. 5). Optical properties of

217     crocobelonite, measured in $AsBr_3$-S immersion liquids, are provided in Table 1.

218

219

## Chemical composition

220

221      Crocobelonite shows rather uniform composition; chemical zoning has never been observed. EMPA

222      data for holotype material of both polymorphic modifications are summarized in Table 2. Iron is

223      calculated as $Fe^{3+}$ according to charge balance, taking into account the absence of water (Raman

224      spectroscopy results) and crystal structure determinations which require the presence of 9 oxygen

225      atoms per formula unit. The empirical formula of holotype crocobelonite-2*O* from Jordan

226      (calculated on the basis of 9 O *apfu*) is $Ca_{1.02}(Fe^{3+}_{1.94}Mg_{0.05}Al_{0.02})_{2.01}(P_{1.98}Si_{0.02})_{2.00}O_{9.00}$; holotype

227      crocobelonite-1*M* from Israel has the empirical formula

228      $Ca_{0.99}(Fe^{3+}_{1.85}Ni_{0.04}Ti_{0.04}Al_{0.03}V^{3+}_{0.02}Cr_{0.01}Mg_{0.01})_{2.00}P_{2.01}O_{9.00}.$ The ideal formula of crocobelonite is

229      $CaFe^{3+}_2(PO_4)_2O$. The comparison of compositions reveals slightly elevated contents of transition

230      metal impurities (Ni, V, Cr, Ti) in crocobelonite-1*M* from Israel. However, the presence of these

231      impurities can not be considered as a factor which determines stabilization of monoclinic polymorph

232      of crocobelonite. EMPA data obtained on the intergrowths of 2*O* and 1*M* polytypes show that they

233      are indistinguishable by the chemical composition.

234

## Crystal structure and powder diffraction

236 X-ray single-crystal study of crocobelonite-2*O* showed that this polymorphic modification is

237 isotypic with synthetic oxyphosphates of trivalent vanadium $A$V$_2$O(PO$_4$)$_2$, where $A$ = Cd, Ca, Sr

238 (Boudin et al. 1994, 1995, 1996) (Table 3). However, the attempts of obtaining high quality SCXRD

239 data for this polymorph were unsuccessful, due to the crystal splitting manifested by the appearance

240 of electron density phantoms ($\geq 3$ $e$ Å$^{-3}$) on the difference Fourier maps. In order to inspect the

241 validity of SCXRD model, we have performed Rietveld refinement of powder diffraction profile of

242 crocobelonite-2*O* (Fig. 6 and CIF file in Supplementary Information). The refinement has confirmed

243 that this is a $Fe^{3+}$ analogue of synthetic compound $CaV^{3+}_2O(PO_4)_2$ (Boudin et al. 1994). Contrary to

244    the orthorhombic polymorph, crocobelonite-1$M$ forms perfect crystals, which allowed conducting

245    single-crystal structure solution and refinement. This polymorphic modification has no direct

246    structural analogues, among neither natural nor synthetic phosphates. The crystal structures of both

247    polymorphs show almost the same topology, with the same coordination of cation sites (Fig. 7,

248    Table 4). Similar to synthetic phosphates $A$V$_2$O(PO$_4$)$_2$ (Boudin et al. 1996), crystal structures of

249    crocobelonite-2$O$ and -1$M$ can be described as tridimensional frameworks [Fe$_2$P$_2$O$_9$]$^\infty$ composed of

250    two kinds of structural subunits. The infinite chains (rods) of edge-sharing Fe(1)O$_6$ octahedra,

251    propagating along the $b$-axis in both polymorphs (Fig. 7), have the same topology as [TiO$_6$] rods in

252    the rutile structure and hence are known as "rutile-like chains" (e.g., Baur 2007). The second type of

253    subunit is comprised by the infinite chains [Fe(2)PO$_8$], also running along the $b$-axis and composed

254    of corner-sharing Fe(2)O$_6$ octahedra and PO$_4$ tetrahedra. Calcium atoms occupy the $b$-axis channels

255    in the [Fe$_2$P$_2$O$_9$] framework. The P(1)O$_4$ tetrahedron shares common edge with Fe(1)O$_6$ octahedron

256    and common corners with Fe(2)O$_6$ octahedron. The P(2)O$_4$ tetrahedron is corner-sharing with two

257    Fe(1)O$_6$ octahedra, Fe(2)O$_6$ octahedron and Ca-polyhedron (Fig. 8). The structural relationship

258    between the polymorphs can be considered a type of "unit-cell twinning", well known in some

259    silicate systems (e.g., Ito 1950; Yau and Peacor 1986). The differences between the unit-cell

260    stacking in crocobelonite-2$O$ and crocobelonite-1$M$ are illustrated in Fig. 9. X-ray powder

261    diffraction data for crocobelonite polymorphs are presented in Tables 5 and 6. The low- to mid-

262    range regions of powder XRD profiles (Fig. 10) can be used to distinguish crocobelonite-2$O$ from

263    crocobelonite-1$M$.

264

265                                   **Raman spectroscopy**

266    The Raman spectra of crocobelonite are shown in Fig. 11. The fingerprint regions (Fig. 11a) contain

267    the groups of bands characteristic of inorganic orthophosphates (Table 7) (Nakamoto 2008, 2009).

12

268 The absence of bands in the O–H stretching region (3800–3000 cm$^{-1}$) and bending modes of

269 molecular $H_2O$ (1630–1670 cm$^{-1}$) (Fig. 11b) evidences for the absence of water in the mineral

270 composition, in accordance with the chemical, structural and optical data.

271

272 **Implications: crocobelonite and the new type of phosphate mineralization**

273 Crocobelonite, $CaFe^{3+}_2(PO_4)_2O$, is an example of natural oxyphosphate (oxophosphate) – the

274 mineral whose chemical formula contains the so-called "additional" oxygen atom(s) (e.g.,

275 Krivovichev 2008). Of more than 600 mineral species belonging to the phosphate class

276 (Krivovichev 2021), oxyphosphates without other anions were, up to date, represented by three

277 minerals: staněkite $(Fe^{3+},Mn^{2+},Fe^{2+},Mg)_2(PO_4)O$ (Keller et al. 1997), grattarolaite $Fe^{3+}_3(PO_4)O_3$

278 (Cipriani et al. 1997), and joosteite $Mn^{2+}(Mn^{3+},Fe^{3+})(PO_4)O$ (Keller et al. 2007). In contrast, the

279 number of their nearest analogues – oxyarsenates (oxoarsenates) – approaches 20 minerals (Davis et

280 al. 1965; Moore and Araki 1978; Vergasova et al. 2000; Roberts et al. 2001; Mills et al. 2010; Pekov

281 et al. 2018, 2019a,b, 2021a,b; Shablinskii et al. 2018). The family of oxyarsenate minerals owes its

282 diversity to a specific type of mineralization connected to arsenic-rich volcanic fumaroles, whose

283 environment favours the formation of high-temperature anhydrous oxysalts (Pekov et al. 2018).

284 However, the very first discoveries of natural oxyarsenates were confined to other mineralization

285 type – the arsenide ores that underwent dry oxidation at high temperatures, the process known in ore

286 mineral processing as pyrolytic oxidation (roasting) (e.g., Dunn and Chamberlain 1997). These

287 assemblages represent, in fact, the combustion products of ores containing nickeline NiAs,

288 skutterudite $(Co,Ni)As_3$, safflorite $CoAs_2$, and rammelsbergite $NiAs_2$. The first described mineral in

289 this family was aerugite $Ni_{8.5}(AsO_4)_2AsO_8$ (Bergemann 1858; Davis et al. 1965; Fleet and Barbier

290 1989), followed by a discovery of paganoite $NiBiAsO_5$ (Roberts et al. 2001). The origin of these

13

291 assemblages, also containing other anhydrous Ni-Co arsenates and bunsenite (natural NiO), was

292 discussed by Kampf et al. (2020).

293      Taking into account the chemical proximity of arsenic and phosphorus, one could expect that

294 the processes similar to high-temperature roasting of arsenide ores could also occur within natural

295 phosphide assemblages. The combination of factors, which would allow the onset and maintenance

296 of such processes, is quite exotic: it must involve the presence of phosphides (which are very rare in

297 nature), highly oxidative conditions and high temperatures. The synthetic $V^{3+}$ analogue of

298 crocobelonite-2$O$ (Boudin et al. 1996) was obtained at temperature 1100 °C - the level that can be

299 used for the estimation of crocobelonite formation conditions. This value looks reasonable as it lies

300 in between the assumed formation temperatures of natural Fe-Ni phosphides – 800–900 °C (Britvin

301 et al. 2020ab, 2021b, 2022a) and the temperatures of at least 1450 °C which took place during

302 solidification of rock-forming mineral assemblages in the Hatrurim Formation (Sharygin et al.

303 2016). This value is considerably higher than the range of 500-750 °C assumed for the formation of

304 volcanic fumarolic arsenates (Pekov et al. 2018). Such unusual formation environment was realized

305 during the pyrometamorphic processes occurred in the Hatrurim Formation, that resulted in the

306 emergence of a new type of phosphate mineralization (Britvin et al. 2021a), in which crocobelonite

307 represents the first oxyphosphate species.

559

560    **Figure 1.** The territory of the Middle East. The fields of the pyrometamorphic rocks belonging to

561    the Hatrurim Formation (the Mottled Zone) are indicated by red areas and circles, with two localities

562    of crocobelonite (the Hatrurim Basin in Israel and Daba-Siwaqa complex in Jordan). Adapted from

563    Britvin et al. (2021a).

564

565    **Figure 2.** The phosphorite quarry in the Daba-Siwaqa complex – the type locality for crocobelonite-

566    2*O*. (a) The overview of the outcrop containing crocobelonite. (b) The black xenolith of partially

567    assimilated phosphorite within the olive-coloured hornfel. (3) The veinlets of bluish-green

568    fluorapatite in a block of varicolored hornfel.

569

570    **Figure 3.** Crocobelonite in phosphate-phosphide assemblages from the phosphorite quarry at the

571    Daba-Siwaqa complex, Jordan (the type locality). (a) The overview of a typical sample of

572    phosphate-bearing paralava. (b) Diopside crystals filling up the paralava. Thin section, transmitted

573    light, XPL. (c) Diopside clumps within the same paralava sample. Thin section, PPL. (d) Cross-

574    section of a typical phosphate-phosphide bearing bubble within paralava. Red areas are

575    crocobelonite aggregates. Thin section, scattered light. (e) Chondrule-like segregations of calcium

576    silicophosphates (indicated as Ch within the bubble in Fig. 3d). Thin section, transmitted light (f)

577    The detail of crocobelonite-bearing area shown in Fig. 3d. Abbreviations: Di – diopside, Ph –

578    phosphides, Hem – hematite, Ch – hondrules, Ccb – crocobelonite.

579

26

580 **Figure 4.** Crocobelonite crystals in the paralava microcavities. (a) Aggregates of prismatic crystals

581 intergrown with hematite (black) and diopside (white). (b) Prismatic crocobelonite crystal.

582 Phosphorite quarry, Daba-Siwaqa complex, Jordan.

583

584 **Figure 5**. Two polymorphic modifications of crocobelonite in a complex phosphate assemblage.

585 Nahal Halamish, Hatrurim Basin, Negev Desert, Israel. (a) Phosphate-bearing nest;

586 photomicrograph of a polished section in scattered light. (b) The same field in reflected light. (c)

587 SEM BSE image of the area. The highlighted rectangle outlines the area subjected to EBSD

588 mapping. (d) EBSD crocobelonite phase map of an area highlighted in (c), superimposed onto BSE

589 image. The red patches denote clinocrocobelonite; the yellow ones correspond to crocobelonite. (e)

590 EBSD IPF (inverse pole figure) map. The different colours correspond to different orientations of

591 crocobelonite crystals. Legend: M –crocobelonite-1$M$; O – crocobelonite-2$O$; Ald – unnamed

592 alluaudite-group phosphate; Hm – hematite; Glass – Ca-Si-P-O glass.

593

594 **Figure 6.** Rietveld refinement plot for crocobelonite-2$O$.

595

596 **Figure 7.** Crystal structure of crocobelonite, in projection that emphasizes structural similarity of

597 both polymorphs. The unit-cell axes of crocobelonite-2$O$ are shown in blue; the axes of

598 crocobelonite-1$M$ are black. A three-dimensional framework composed of two types of structural

599 subunits. The first one is represented by the infinite "rutile-like" chains (rods) of edge-sharing

600 Fe(1)O$_6$ octahedra, propagating along the $b$-axis in both polymorphs. The second type of subunit is

601 comprised by the infinite chains [Fe(2)PO$_8$], also running along the $b$-axis and composed of corner-

602 sharing Fe(2)O$_6$ octahedra and PO$_4$ tetrahedra. The rods are connected into a framework via the

603 inter-rod [FeO$_6$] octahedra and [PO$_4$] tetrahedra together with [CaO$_7$] polyhedra (the latter are not

604 shown for clarity). Legend: [FeO$_6$] – red; [PO$_4$] – yellow.

605

606 **Figure 8.** Fragment of crocobelonite structure showing the linkages between tetrahedral [PO$_4$] and

607 octahedral [FeO$_6$].

608

609 **Figure 9.** Structural relationship between crocobelonite polymorphs. Projections onto {010}. (a)

610 Crocobelonite-1*M*. The unit cell is highlighted by gray colour. (b) Crocobelonite-2*O*. The unit cell is

611 highlighted by blue colour. Stacking of building sub-layers in crocobelonite-2*O* can be expressed as

612 the "unit-cell twinning" of crocobelonite-1*M* cells, where the "twinned" 1*M* cells are related by the

613 mirror plane {100} and half-cell translation along the *c*-axis (in orthorhombic setting). Legend:

614 [FeO$_6$] – red; [PO$_4$] – yellow.

615

616 **Figure 10.** The mid-angle ranges of powder X-ray diffraction patterns of crocobelonite-1*M* and

617 crocobelonite-2*O*. Note the substantial differences in the patterns due to the differences in the crystal

618 structures and lattice geometries.

619

620 **Figure 11.** Raman spectra of crocobelonite polymorphs. (a) The fingerprint region. (b) The high-

621 frequency part beyond 1500 cm$^{-1}$. The absence of vibrations in the OH-stretching region indicates

622 for the lack of hydroxyl water.

623

624

648

649    [a] Site labelling corresponds to synthetic $CaV_2(PO_4)_2O$ (Boudin et al. 1995). Bond-valence parameters
650    were taken from Brese and O'Keefe (1991), assuming that Fe sites are populated with $Fe^{3+}$.
