### ABSTRACT

The heat capacity of three synthetic polycrystalline almandine garnets (ideal formula  $\text{Fe}_3\text{Al}_2\text{Si}_3\text{O}_{12}$ ) and one natural almandine-rich single crystal was measured. The samples were characterized by optical microscopy, electron microprobe analysis, X-ray powder diffraction, and Mössbauer spectroscopy. Measurements were performed in the temperature range 3 to 300 K using relaxation calorimetry and between 282 and 764 K using DSC methods. All garnets show a prominent  $\lambda$ -type heat-capacity anomaly at low temperatures resulting from a paramagnetic-antiferromagnetic phase transition. For two  $\text{Fe}^{3+}$ -free or nearly  $\text{Fe}^{3+}$ -free synthetic almandines, the phase transition is sharp and occurs at 9.2 K. Almandine samples that have ~3%  $\text{Fe}^{3+}$  show a  $\lambda$ -type peak that is less sharp and that occurs at  $8.0 \pm 0.2$  K. The low- $T C_p$  data were adjusted slightly using the DSC results to improve the experimental accuracy. Integration of the low- $T C_p$  data yields calorimetric standard entropy,  $S^\circ$ , values between  $336.7 \pm 0.8$  and  $337.8 \pm 0.8$  J/(mol·K). The smaller value is recommended as the best  $S^\circ$  for end-member stoichiometric almandine, because it derives from the “best”  $\text{Fe}^{3+}$ -free synthetic sample.

The lattice (vibrational) heat capacity of almandine was calculated using the single-parameter phonon dispersion model of Komada and Westrum (1997), which allows the non-lattice heat capacity ( $C_{\text{ex}}$ ) behavior to be modeled. An analysis shows the presence of an electronic heat-capacity contribution ( $C_{\text{el}}$ , Schottky anomaly) superimposed on a larger magnetic heat-capacity effect ( $C_{\text{mag}}$ ) around 17 K. The calculated lattice entropy at 298.15 K is  $S_{\text{vib}} = 303.3$  J/(mol·K) and it contributes about 90% to the total standard entropy at 298 K. The non-lattice entropy is  $S_{\text{ex}} = 33.4$  J/(mol·K) and consists of  $S_{\text{mag}} = 32.1$  J/(mol·K) and  $S_{\text{el}} = 1.3$  J/(mol·K) contributions. The  $C_p$  behavior for almandine above 298 K is given by the polynomial [in J/(mol·K)]:

$$C_p = 649.06(\pm 4) - 3837.57(\pm 122) \cdot T^{-0.5} - 1.44682(\pm 0.06) \cdot 10^7 \cdot T^{-2} + 1.94834(\pm 0.09) \cdot 10^9 \cdot T^{-3}$$

which is calculated using the measured DSC data together with one published heat-content datum determined by transposed-drop calorimetry along with a new determination in this work that gives  $H_{1181\text{K}} - H_{302\text{K}} = 415.0 \pm 3.2$  kJ/mol.

Using our  $S^\circ$  value and the  $C_p$  polynomial for almandine, we derived the enthalpy of formation,  $\Delta H_f^\circ$ , from an analysis of experimental phase equilibrium results on the reactions almandine + 3rutile = 3ilmenite + sillimanite + 2quartz and 2ilmenite = 2Fe + 2rutile +  $\text{O}_2$ . A  $\Delta H_f^\circ = -5269.63$  kJ/mol was obtained.
